

**DEVELOPMENT OF EMPIRICAL MODELS FOR ESTIMATING  
TBM PENETRATION RATE IN ROCK MASS**

**Aitolkyn Yazitova**

Lead Supervisor: Prof. Saffet Yagiz

Internal Co-supervisor: Prof. Amoussou C. Adoko

External Co-supervisor: Prof. Jafar Hassanpour

A thesis submitted in fulfillment of the requirements for the degree of  
Doctor of Philosophy in Mining Engineering

**Department of Mining Engineering**

**School of Mining and Geosciences**

**May 2025**

## **Originality statement**

“With this statement I hereby confirm that the submitted research proposal is my own work. To the best of my knowledge, it contains no sources or resources previously published or written by another person. Any contribution has been made to the research by others, with whom I am working at Nazarbayev University, explicitly will be acknowledged in the thesis. I have indicated all quotes, citations and references that were literally taken from publications, such as, academic articles, whether published or unpublished, as well as web sources, reports, papers, etc.”

Date: 03.05.2025

Signature:

## **Dedication**

I would like to express my deepest and most heartfelt gratitude to my friends who have stood by me and shared in every step of this journey. Your encouragement, companionship, and unwavering belief in me have been a source of strength and inspiration throughout this project.

Above all, my most profound thanks to my beloved parents, Maxat Kuspanov and Aliya Kuspanova. Your constant love, sacrifices, and steadfast moral support have shaped the person I am today. You have been my guiding light in every challenge and triumph, and this accomplishment would not have been possible without you.

With all my love, respect, and devotion,

*Aitolkyn Yazitova*

## **Acknowledgments**

I would like to begin by extending my heartfelt gratitude to my supervisor, Prof. Saffet Yagiz, whose unwavering support, insightful feedback, and expert guidance have been instrumental throughout my PhD journey. His encouragement and mentorship have been a cornerstone in the successful completion of this thesis. I am equally grateful to my co-supervisor, Prof. Amoussou C. Adoko, for his dedication, patience, and invaluable insights. His willingness to devote countless hours to consultations and guidance has greatly enriched my work and contributed significantly to this achievement. I also thank to Prof. Jafar Hassanpour who was my external Co-Supervisor and also provided raw data from Iranian TBM tunnel projects for this study. Also, I would like to extend my sincere thanks to reviewers, Prof. Nasser Madani, Prof. Sergei Sabanov and also Prof. Murat Karakus who was kindly accept our invitation for the committee. Further, I would like to extend my gratitude the Nazarbayev University who provided fund via Faculty Competitive Grant Project (Grant No: 021220FD5151) for this research.

## **Abstract**

Estimating the Rate of Penetration (ROP) of Tunnel Boring Machines (TBMs) is crucial in rock excavation and boreability, as it serves as a key input for scheduling and executing tunneling projects. Despite advancements in tunneling technologies, achieving a reliable ROP estimate remains challenging. In present one of the difficult tasks is to quantifying the properties of rock discontinuities to be use as input for the TBM performance models. Another issue is that utilizing the combination of intact rock, rock mass properties and TBM specification into the TBM performance prediction models.

This thesis aims to develop several empirical models using intact rock, rock mass, disc cutter and TBM specifications for predicting TBM penetration rates in hard rock conditions. In order to achieve this goal, extensive field and laboratory tests were conducted across six TBM projects, including the Queens Water Tunnel (USA), Manapouri hydropower tunnel (New Zealand), Miryang dam tunnel (South Korea), and three Iranian water tunnels (Karaj, Zagros and Ghomrood), resulting in a database of more than 550 cases. Each case consists of the intact rock, rock mass properties and TBM field parameters. The collected data underwent preprocessing and analysis. The raw data were thoroughly examined with the literature to ensure the research output was valuable and acceptable. Common TBM performance models used by researchers and industry were critically reviewed.

In order to develop the models, first of all, a rock mass fracture index (FI) was introduced using a weighting method. Then, numerous linear and nonlinear multivariable regression models were developed using the SPSS program. At least a hundred models were generated for the aim; then the best twenty of them were chosen for each case by means of the linear multiple regression (LMR) and Non-linear multiple regression (NLMR) to be evaluated and introduced. After examination of LMR and NLMR models, with the

top five models evaluated using performance indices and a total ranking approach introduced in the thesis, the rest of them are provided in the appendices. Six statistical measures—coefficient of determination, root mean square error, mean absolute deviation, mean absolute percentage error, relative root mean square error, and variance accounted for—were used to rank the models. The study confirmed that estimating TBM penetration rate is a complex, non-linear issue due to the heterogeneous nature of rock masses. The most accurate model was a NLMR with fewer input variables, achieving the highest-ranking score of 42 (Eq.5.17; Model 1-NLMR). This model, incorporating intact rock strength, a weighted fracture index, and operational machine parameters, was ultimately identified as a reliable tool for TBM tunneling. Finally, it is concluded that the introduced rock fracture index (FI) together with weighted fracture index (WFI) could be used for quantifying the discontinues of rock mass into the TBM performance prediction model to represent the rock mass parameters. Further, it is found that the developed model could be used for similar rock type and geological formation in practice; More, it is suggested that the alpha angle, that is the angle between plane of weakness including joint, faults and shear zone and TBM driving direction, could be added as an input into the model to obtain the more accurate result for project scheduling in practice.

## CHAPTER 1 : INTRODUCTION

### 1.1. Background

Mechanized excavation refers to the method of rock breakage where the rock is entirely removed from the excavation face by mechanized excavators. The characteristic advantages of mechanical excavation over a traditional drilling and blasting are increased safety, higher production rate, reduce labor-intensive operation, higher degree of automation, minimum damage to the walls, better control over the process, uniformity of product size, elimination of blast vibrations, and better ventilation in underground openings with a length of over 1.5 km in almost all ground conditions from weak through the hard rocks. The most common types of mechanized excavators are tunnel boring machines (TBMs), roadheader (RH), raise boring machine (RBM), continuous miner (CM), and longwall drum shear (LDS) to be used for either civil or mining construction. Depending on the ground condition, one of those excavators could be chosen to excavate rocks for variety of purposes such as drift development, ventilation shaft, highway, dam, or ground water transportation tunnels. Even though numerous models have been proposed for prediction of rate of penetration (ROP), the accuracy of the developed models for the aim depends on the original database from which they were driven, range of dataset used for the model as well as ground condition, type and specifications of excavator utilized in project.

For construction planning and for the selection of the most suitable excavation technology, the estimation of the TBM performance, in terms of rate of penetration (ROP), utilization factor (U), daily advancement (AR) has become significant parameters that should be measured or estimated for project scheduling related to time and cost implication. TBM performance assessment is a complex and non-linear problem to be

solved as real-world project scheduling due to that it is not simply can be estimated as a function of simple one parameter. Developed function for the aim should be non-linear with multiple input variables to obtain the most accurate output such as ROP, U and AR.

During the last decades a number of models have been developed for the prior-to-construction prediction of the TBM performance based on input parameters including intact rock, rock mass parameters and also TBM specifications (Table 1.1). In present, several models including Colorado School of Mines, CSM (Rostami, 1997; Cheema 1999; Yagiz, 2002), Norwegian University of Sciences and Technology, NTNU (Bruland, 1998; Macias et al. 2014; Macias, 2016), field penetration index (FPI) (Nelson et al. 1983; Hassanpour, et al. 2011),  $Q_{\text{tbm}}$  Model (Barton, 1999), Alpin Model (Gehring, 1995; Wilfing, 2016) can be mentioned herein. In fact, TBM performance prediction models can be divided into three main approaches, namely, theoretical and empirical models as well as artificial intelligence (AI).

Table 1.1. Common parameters influencing TBM penetration in the literature

Intact rock parameters	Rock mass parameters	Machine parameters
Uniaxial compressive strength	Rock mass fabric	Total thrust ( $F_t$ )
Point load Index	Rock texture	Normal force ( $F_n$ )
Brazilian tensile strength	Orientation of discontinuities	Cutter diameter
Rock brittleness, Toughness	Spacing between the fractures	Cutter tip width, RPM
Hardness	Rock Quality Designation	Spacing between the cutters
Drilling rate index (DRI)	Fissures	Number of Cutters
Thin section analysis	Grain size and minerals	Cutterhead Power

## 1.2. Problem Statement

TBM performance estimation prognosis be divided in two main categories: the empirical models, which represent the largest group with field and laboratory studies,

and the theoretical or semi-theoretical models refers to a basic understanding of rock fragmentation and explanations into the force versus penetration behavior of rocks. Due to the complexity of TBM performance prediction, artificial intelligence (AI) methods particularly machine learning algorithms also conducted in the literature (Grima, et al. 2000; Benardos and Kaliampakos, 2004). Even though numerous empirical, mathematical, Artificial Intelligence (AI) models were introduced in the literature, most of them are based on the rough dataset of one or two projects, simple correlations between two variables (such as ROP vs UCS) or without proper rock mass discontinuity properties that directly influence the ROP.

In order to address significance of input parameters (intact rock strength and TBM specification) and use them together with quantified rock fracture properties, this research is conducted based on six long mechanized tunnel projects where the database is developed. With this research, input variables are chosen, rock fracture index were developed and all together used for estimating the TBM performance in empirical approaches using statistical program.

### **1.3. Research Objectives**

The main aim of this research is to develop several new empirical models which is powerful and useful in practice for predicting the ROP of TBM based on uniaxial compressive strength (UCS) of intact rock and rock fracture index (FI) measured in the field and TBM specification and cutter disc properties. To obtain the aims, the following are accomplished:

- Raw UCS data, rock mass data and TBM field data were obtained from six TBM tunnel projects including Queens fresh water (USA), Manapouri Hydropower (New Zeland), Miryang dam (S. Korea) and Iranian fresh water transfer tunnels (Iran).

- Obtained raw data is examined and then the database established base on available parameters including UCS, spacing between the discontinuities in rock mass, RPM, cutterhead diameter, power, torque and thrust of TBM as well as disc diameter, and individual cutter load.
- Introducing the rock fracture index (FI), weighted fracture index (WFI) and then examine the impact of each individual variable in the database on the estimation of the ROP
- Apply SPSS Statistics program to develop possible multiple variables linear and non-linear models for estimating the ROP.
- Check the validity of developed models and compare them to suggest the best one to be used for real world mechanized excavation project.

#### **1.4. Thesis Organization**

This is composed of several chapters that is related to from aim of it through the conclusions as follow:

**Chapter 1: *Introduction*** section of this research, in which the background of the research, problem statement, research objectives and thesis organization is presented.

**Chapter 2: *Comprehensive Literature Review*** related to general through the detail aim of the research which is about data analysis and TBM performance estimation. The chapter provides information related to current main input parameters and their influence on the estimated ROP as well as current models for estimating the ROP in the literature.

**Chapter 3: *Case Studies*** including geological and rock mass properties of the project. Laboratory and field observation of rock features and TBM specification and performance. General project overview of six TBM tunnel projects studied and investigated for the aim.

**Chapter 4: *Development of Rock Fracture Index*** and weighted fracture index as an input parameter related to discontinuities of rock mass for the estimation of TBM performance from weak through the hard rock mass conditions.

**Chapter 5: *Development of Empirical Linear and Non-linear Multivariable Models*** for estimating the TBM penetration rate. This section includes linear and non-linear multivariable regression models for the aim which is estimating the ROP. Then, comparing the obtained alternative models to suggest the best one among them.

**Chapter 6: *Application and Limitations*** that focus on application of developed models and their limitations that is related to rock and TBM specification as well as rock conditions.

**Chapter 7: *Conclusions and Recommendations***. This section refers to conclude the output of this thesis, suggested model among the ones for the aims and also recommendations for future studies.

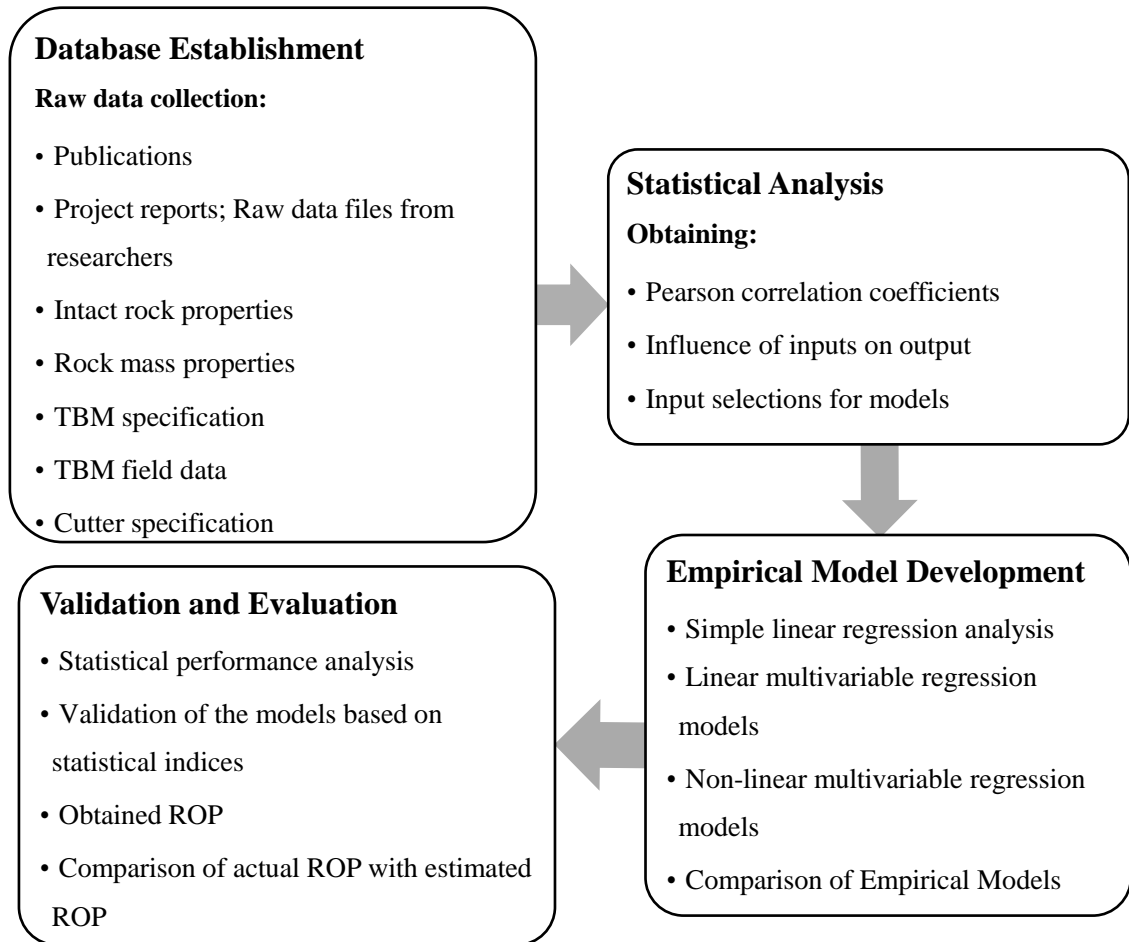

Figure 1.1. Diagram illustrated to research design

## CHAPTER 2 : LITERATURE REVIEW

Since 1950's, many improvements have been carried out on the design of TBM and to improve the machine advancement (Figure 2.1). These changes have led to more powerful and efficient TBMs in a variety of ground conditions, from very hard to soft rocks having UCS of 80MPa to more than 300MPa respectively. For any tunneling project, one of the challenging issues is predicting the performance of TBM in difficult ground conditions (Nelson, 1993; Sapigni et al. 2002). Geological record and mapping provide valuable quantified and unquantified information about the geological conditions ahead of the tunnel face and the response of the rock mass to excavation progress. Rock mass weathering, intact rock strength (both UCS and BTS), geological structures and other conditions influence TBM performance in tunnelling project (Sapigni et al. 2002; Benardos and Kaliampakos, 2004). Therefore, prediction of TBM penetration is very crucial in planning the tunnel projects and selecting the suitable methods of construction, and it can decrease the risks related to high capital costs, which are very common for the mechanized excavation operations (Yagiz, 2002; Yagiz et al. 2009). A key component in the successful planning of TBM tunnelling is the accurate prediction of TBM performance parameters, the penetration rate (PR) and the advance rate (AR). Over the past few decades, there have been numerous research studies conducted, most of them in the developed countries such as USA, Germany and Norway, to estimate TBM performance in rock mass. At present, estimation of TBM performance may be made by means of penetration rate (ROP), the ratio of excavated distance to the operating time during continuous excavation phase, and advance rate (AR), the ratio of both mined and supported actual distance to the total time or field penetration index (FPI), that is the ratio of individual cutter load to RoP (Rostami, 1997; Yagiz, 2002; Hassanpour, et al. 2009, 2011; Adoko, et al. 2017; Yazitova, et al. 2025). Rostami (2016) stated that predicting

the performance of Tunnel Boring Machines (TBMs) is crucial for effective project scheduling and cost estimation. This process requires a deep understanding of the geological complexities of the site, the specifications of the machine, and site management practices. Over the years, various methods have been employed to estimate TBM performance in specific ground conditions. While many of these methods have proven to be accurate within acceptable limits, some have significantly deviated from the actual performance. Experience indicates that the most reliable approach to predicting TBM performance is to use multiple models to assess a range of estimated penetration and advance rates, and then select the rate that best aligns with the actual working conditions and the parameters of the model used. This strategy helps engineers avoid unexpected issues and identify the key factors influencing machine performance in each situation. The chapter reviews type of TBMs, intact rock, rock mass properties, disc and TBM operational parameters, and also the existing models for TBM performance prediction and discusses ongoing research aimed at developing more accurate models to enhance TBM performance.

Figure 2.1. TBM thrust and torque system respectively (Nelson, 1993)

## 2.1. Type of Tunnel Boring Machine (TBM)

Various types of TBMs are in use today for the full-face excavation in rock condition from weak, medium to hard rocks. Since the research is related to TBMs,

general specification of the different type of TBMs are herein together with ground condition where selected type of TBM could be productive and applicable. Different TBMs may be selected on the ground condition from hard rock through the fractured rock with groundwater inflows (Figure 2.2).

Figure 2.2. Geological condition of ground condition and suggested TBM (Robbins Company)

Further, one of the most important distinctions in hard rock TBM classification is between the open (gripper) and the shield TBM as follow.

**2.1.1. Open TBMs**

The open type TBM, also called gripper TBM, is widely used for tunnel excavation where rock masses are characterized by good quality, rock strength can be characterized by medium to high strength, and stand-up time long enough to put in work the required supports in safety conditions. During the boring operation, two laterally mounted gripper plates anchor the rear part of the machine to the tunnel side walls, while the rotating cutterhead having disc cutters is pressed against the tunnel face. Due to the rolling movement of the cutters, single pieces (chips) of rock are cut out from the face and removed. The demonstration of Open TBMs is presented in Figure 2.3 where TBM has different type of component and each of them illustrated herein.

Figure 2.3. Principal components of Open TBMs (Chen et al. 2023)

### 2.1.2. Shielded TBMs

This group of TBMs is usually used to excavate jointed rock masses with low stand-up time; in these contexts, single shield TBMs can guarantee high tunnelling performances.

Figure 2.4. Principal components of a shield TBM (Chen et al. 2023)

The substantial difference between open and shield TBM is that in the first group the contrast required by thrust cylinders to transfer the thrust to the cutterhead is provided by rock tunnel walls, whereas in the second group the contrast is provided by lining, given that rock mass strength in which single shield TBMs are used generally lower than the one characterizing the rock mass in which open TBM are adopted (Paltrinieri, 2015). This TBM is applicable for rock characterized by low to high strengths. The demonstration of Shield TBMs is presented in Figure 2.4 where TBM has different type of component and each of them illustrated herein.

### **2.1.3. Double shielded TBMs**

Double shield TBMs, also called telescopic shields, are frequently used in long tunnel excavation in hard rocks with high fractured or shear zones and/or fault zones in rock mass. The double shield TBMs are considered the most sophisticated ones because they are a combination of gripper and single shield machines. They guarantee very high tunnelling performances by working in continuous tunnelling method. They consist of two principal elements: a front shield with cutterhead, drive and main bearing; and a gripper shield with gripping units, auxiliary thrust cylinders, tail skin (Maidl et al. 2008) as shown in Figure 2.5. The two parts of the shield are connected by the main thrust cylinders and a telescopic shield protects them. The segments are installed in the tail skin section while the machine is tunnelling. When a bore stroke is completed the gripper, shoes are loosened and the auxiliary thrust cylinders make the gripper shield push behind the front shield.

The TBM simultaneously excavates and erects the tunnel lining (continuous cycle of excavation). The machine unifies the functional principles of gripper and single shield TBMs being equipped by two possible “thrust systems” which is adopted on the basis of the ground conditions: the jacks that push against the segment ring to create the thrust

for the TBM as well as the grippers (located on the second shield) that push against the excavated tunnel. In this sense the double shield machine can be considered as one of the most flexible types of machine. The demonstration of double shield TBMs is presented in Figure 2.5 where TBM has different type of component and each of them illustrated herein.

Figure 2.5. Principal components of a double shield TBM (Chen et al. 2023)

Table 2.1. Comparison between open TBM and shield TBM (Chen et al. 2023)

Comparison items	Open TBM	Double-shield TBM	Single-shield TBM
Geological adaptability	It is generally used in good geological conditions, featuring good adaptability to hard rock tunneling. In soft rock, stratum shall be reinforced in advance. It is suitable for tunnels dominated by Class II and III rocks	Its adaptability to hard rock tunneling is the same as that of open type. In soft rock tunneling, single shield is better than open type. It is suitable for tunnels dominated by Class III rocks	It is used under relatively poor geological conditions (but the excavation face can be self-stabilized). It is suitable for tunnels dominated by Class III and IV rocks
Tunneling performance	On the premise of giving full play to the advance speed, it is mainly suitable for hard rock stratum (50–150 MPa) with relatively complete to complete rock mass and good self-stability. When effective support measures are adopted, it can also be applied to soft rock tunnels, but the advance speed is limited	On the premise of giving full play to the advance speed, it is mainly suitable for soft rock to medium hard rock stratum (30–90 MPa) with relatively complete rock mass and certain self-stability	It is suitable for soft rock (5–60 MPa) with certain self-stability in medium-length
Construction speed	Only bolting and shotcreting is needed if the geological conditions are good. In this case, the supporting workload is small and the speed is fast. However, it needs to be reinforced in advance if the geological conditions	When the geological conditions are good, the tunnel wall is supported by grippers to provide the reverse thrust, and the tunneling and installation of the segment are carried out at the same time to speed up the progress. In soft ground, single	Tunneling and segment installation cannot be carried out at the same time, so the construction speed is limited

	are poor. In this case, the supporting workload is large and the speed is slow	shield tunneling is adopted, and tunneling and segment installation cannot be carried out at the same time, so the construction speed is limited	
Safety	Equipment and personnel are exposed to rocks, so protection should be strengthened	Personnel safety can be secured under the protection by shield. There is a danger of being stuck when the ground stress is high and the stratum is broken	Personnel safety can be secured under the protection by shield. There is a danger of being stuck when the ground stress is high and the stratum is broken
Advance speed	It is affected by geological conditions, but	Less affected than the open type	It is less affected by geological conditions than the open TBM
Lining mode	Secondary concrete lining can be carried out depending on specific situation	Segment lining is adopted	Segment lining is adopted
Geological conditions for construction	The lithological change of the tunnel wall can be directly observed during the tunneling process. It is convenient for geological map description. When the geological survey data is not detailed, it is less risky to choose open TBM for construction	It is difficult to systematically describe the construction geological conditions and measure the convergence deformity. The construction risk will be high if the geological survey data is not detailed	It is difficult to systematically describe the construction geological conditions and measure the convergence deformity. The construction risk will be high if the geological survey data is not detailed

## **2.2. Rock Breakage Process**

There have been numerous studies conducted to explain the interaction between rock and mechanical cutting tools as well as the rock fragmentation process during the TBM operation. Rock fragmentation under disc cutter includes different procedures crushing, chipping and fracturing respectively (Rostami and Ozdemir, 1993). Each of these phenomena is representing one of the physical properties of rock and in combination with each other. The linear cutting machine (LCM) test on a rock block and theoretical results confirmed that beneath the CCS disc, three different zones can be observed, namely the crushed zone, the fracture zone, and the elastic zone; however, the most significant zones are crushed and fractured zone in terms of rock fragmentation and breakage. All authors agree that the fragmentation is divided into two parts (Figure 2.6): a zone of crushed material beneath the cutter (crushed zone) and the formation of rock chips (Sanio, 1985; Sato et al. 1991; Rostami and Ozdemir 1993; Yagiz, 2002; Bruland, 1998; Wilfing, 2016; Rostami, 2016; Hassanpour, 2018). Most of the researchers have confirmed and stated that, as the disc cutter penetrates the rock, it creates a crushed zone under a disc cutter; then this zone transfers of stresses applied by disc into the rock medium to initiate the crack. The spacing between joints occurring in a rock mass has a great influence on the chip forming process. The role of joint spacing on rock fragmentation under cutter action has been studied by many researchers (Sanio, 1985; Sato et al. 1991; Yagiz, 2002; Gong and Zhao, 2009; Thuro and Plinninger, 2006) by means of field tests, laboratory tests (e.g. indentation test) and numerical simulation methods.

Figure 2.6. Schematic figure of the fragmentation process during rock excavation with disc cutters (Rostami, 1997; Wilfing 2016)

### 2.3. TBM Performance Parameters

In common, the penetration rate, advance rate, utilization and cutter wear are used to evaluate the TBM performance; however, field penetration rate is also another parameter that can be used for the aim. Main TBM performance parameters utilized to estimate the machine performance in the literature as follow:

The rate of penetration (ROP) or penetration rate (PR) is defined as the excavated length in a continuous phase during the effective boring time; it represents net penetration. This time does not consider TBM maintenance, excavation stop for reinforcement or support element.

$$ROP = \frac{L_e}{T_e} \quad (2.1)$$

Where  $L_e$  is the excavated length and  $T_e$  is the effective boring time. ROP is usually expressed as meter/ hour.

In addition, ROP can be computed based on the distance bored per cutter head revolution; it is defined as an instantaneous penetration or the basic penetration rate (Bruland, 1998). Penetration per cutter head revolution,  $P_{rev}$ , can be used to investigate the mechanics of rock cutting as:

$$P_{rev} = \frac{1000 \cdot ROP}{60 \cdot RPM} \quad (2.2)$$

Where  $P_{rev}$  is penetration per revolution of cutterhead in mm/rev, and RPM is the rate of cutterhead revolutions per minute.

The advance rate (AR), is the ratio between excavated length and total time, which includes the time necessary to bore, to install supports and lining, the time needed for the TBM ordinary and extraordinary maintenance.

$$AR = \frac{L_e}{T_t} \quad (2.3)$$

Where  $L_e$  is the excavated length and  $T_t$  is the total time essential to do all the required operation. AR is usually expressed as meter/ hour.

Utilization (U), which is the ratio between AR and ROP and expressed as percentage (%). In stable rock mass condition, the AR is considerably lower than the ROP and U ranges from 30-50% due to machine daily maintenance.

$$U = \frac{AR}{ROP} \quad (2.4)$$

The field penetration index, FPI, (Nelson, et al. 1983; Tarkoy and Marconi, 1991; Klein, et al. 1995; Hassanpour, et al. 2011) is the ratio between the total force acting on each cutter and the penetration rate per revolution. It represents the force necessary to obtain a determinate penetration during a single individual disc revolution.

$$FPI = \frac{F_n}{ROP_{rev}} \quad (2.5)$$

Where,  $F_n$  is the force acting on each cutter. It can be expressed as kN/cutter/mm/rev

Specific penetration (SP) also represents the performance parameters and it is the inverse of FPI. It can be calculated as:

$$SP = \frac{ROP_{rev}}{F_n} \quad (2.6)$$

Where, SP is measured in mm/rev/kN/cutter acting on each cutter. It is introduced by Alber (2000) with the aim of combining the cutter force and cutter head revaluation.

The specific excavation rate (SER), was developed by Stevenson (1999) to combine the specific penetration and the tunnel cross area, in fact it can be calculated as the ratio between the excavated volume per each cutterhead revolution and the force per cutter.

$$SER = A \cdot SP \quad (2.7)$$

Where, A is the cross-section area of the tunnel. SER is measured in (m<sup>3</sup>/rev)/(kN/cutter).

#### **2.4. Factors Influencing the TBM performance**

During the rock excavation process, many factors affect TBM performance Table 2.2 where listed the important factors. Some factors directly and some of them indirectly influence the rate of penetration.

Table 2.2. Factors influencing TBM performance (Modified from Blindheim, 1979; Salimi, 2021)

Geological/Geotechnical	Machine and Operation	Organization
Rock material properties	TBM specifications	Work arrangements
<ul style="list-style-type: none"> <li>• Strength: compressive, tensile, shear</li> <li>• Crushing strength</li> <li>• Rock toughness</li> <li>• Elasticity, rebound, hardness</li> <li>• Anisotropy</li> <li>• Porosity</li> <li>• Abrasivity</li> <li>•</li> </ul>	<ul style="list-style-type: none"> <li>• Thrust, net and total including friction</li> <li>• RPM, rolling speed</li> <li>• Torque capacity, installed and usable power</li> <li>• Number diameter, edge width, material</li> <li>• Cutterhead diameter, shape, and stiffness</li> <li>• Cutter change mode: front or back-loaded</li> <li>• Re-gripping principle: thrust on walls/roof or on segmented lining</li> </ul>	<ul style="list-style-type: none"> <li>• Available hours, work regulations</li> <li>• Shift schedule, buffer time</li> <li>• Crew organization authority of shift bosses, autonomous groups</li> <li>• Crew training and experience</li> <li>• Crew remuneration, bonus system</li> </ul>

Net penetration is influenced mainly by rock material and rock mass properties and machine parameters such as thrust and cutter spacing. The most important parameters with major impact on TBM penetration can be classified as; Intact rock properties, rock mass properties, ground condition along the tunnel alignment and machine characteristics (power, thrust, torque, shape and disc of disc cutters). Further, Site management and logistics mainly influences utilization of TBM.

#### **2.4.1. Intact Rock Properties**

One of the most influencing parameters is the rock strength; generally, when it increases the penetration decreases and the thrust required to guarantee a penetration is high (Yagiz, 2008; Gong and Zhao, 2009; Hamidi, et al. 2010; Fatemi, 2018; Armetti, et al. 2018). Rock material strength is used as an important parameter in many rock classification systems as well as predicting boreability and drillability of rock (Yagiz, 2002; Salimi, 2021). Hence, the Uniaxial Compressive Strength of rock (UCS) is one of the most important engineering properties of rocks. It should be noted that, prediction models relying only on the UCS of intact rock may provide inaccurate results, since TBM performance is a non-linear function of multiple variables including rock material and rock mass properties and TBM specifications (Yazitova et al. 2025). Tensile strength is another common rock strength property used in making boreability predictions. Brazilian Tensile Strength (BTS) is generally intended to provide an indication of rock brittleness from a viewpoint of crack propagation between adjacent cutter paths (Yagiz, 2008).

As result, the UCS of rock was used to describe the rock crushing beneath the cutter tip while the tensile strength accounted for the chip formation between adjacent cuts (Rostami, 2016). It is remarkable that, great attention should be paid how to the sample failed during UCS or BTS testing whether structural or non-structural failure. Those samples, which were observed to fail along with existing rock defects, such as

joints, fractures, bedding, or foliation, must be classified as a structural failure otherwise should be noted as non-structural failure.

Another rock property, which affects rock boreability is the brittleness that is a highly desirable feature of the rock. In general, the rock cutting efficiency of any mechanical tool improves with increasing brittleness exhibited by the rock formation. Even though brittleness is one of the necessary properties of rock, there is no agreement in the engineering rock mechanics community to describe or measure it. There are several different methods used for the determination of rock brittleness; however, two common methods include the Punch penetration test (Gertsch, 2000; Yagiz, 2009; Yagiz, et al. 2020) and Brittleness value,  $S_{20}$  (Bruland, 1998) were found to influence the boreability of rock when assessing TBM performance (Gong and Zhao 2007; Yagiz, 2002, 2009; Altindag, 2010). Also, using difference alternatives of the ratio of UCS to BTS, the brittleness of rock has been estimated (Hucka and Das, 1984; Altindag, 2010). Among these rock brittleness approaches, Yagiz (2009) and Altindag (2010) were classified in the literature and useful for examining the rock boreability. Further, couple index properties of rock including density and porosity are also important parameters to defined the failure behavior of rock under the compression. More it is known that both these indices are related to brittleness of rock (Yagiz, et al. 2020).

#### **2.4.2. Rock Mass Properties**

The characteristic of the rock mass features and conditions is of major influence for examining the penetration rate of TBM. Rock mass properties are heavily influenced by the rock fabric which is described by discontinuity or cleavage characteristics in the field. Joints, faults, folding, bedding, foliation and any other weakness zone of the rock mass should be considered to examine the TBM performance by quantified features of discontinuities. Main aspect is the orientation of joints, fissures and faults relative to the

direction of tunnel advance herein. The parameter includes the strike direction and the dipping angle of discontinuities and also the distance between these planes of weakness must be considered. Besides rock mass characteristics, also the primary state of stress and the water inflow within the rock mass influence the performance of tunnel boring machines. However, these parameters have not yet been investigated adequately and are until now not implemented into prediction models (Wilfing, 2016). The main characteristics of rock mass that have a significant influence on TBM performance include:

- ***Discontinuity spacing*** that is the most significant rock mass property which has a undoubtedly great role to play on TBM performance. It is easy to realize that discontinuity and its feature can facilitate rock breakage because cracks induced by disc cutters easily develop along the existing discontinuities as compared to extending across the grains (Salimi, 2021). Rock quality designation-RQD (Deer, et al. 1969), Volumetric joints (Palmstrom, 1995), Joint spacing (Js) are three frequently used parameters to describe the discontinuity spacing (Khosravi et al. 2021). Yagiz (2002) also utilized orientation and spacing of fracture to adjust the CSM model basic penetration. The past investigations by the Norwegian University of Science and Technology (NTNU), decreasing joint spacing means the fracture factor ( $K_s$ ) increases which has a direct impact and leads to an increased penetration rate of TBM (Bruland, 1998) as shown at Table 2.3. Barton (2000) in the  $Q_{TBM}$  model, used modified RQD, namely  $RQD_o$  (it must be oriented in the tunneling direction) for predicting TBM penetration. The  $RQD_o$  has a direct relationship with  $Q_{TBM}$  and an inverse relationship with the ROP. Recently, Yagiz, et al. (2024a, b) and Yazitova, et al. (2025) introduced rock fracture index and weighted fracture index to quantify the frequency of fractures in unit length of the excavated tunnel. Yazitova, et al. (2025) stated that rock fractures including faults, joint, foliation, crack

can be quantified as inverse of spacing between the discontinuities in rock mass as number of joints per meter along the tunnel alignment. They named as rock fracture index (FI) and then multiplying the FI with excavated length of the rock is named as weighed fracture index (WFI) as will be discussed further in this thesis.

Table 2.3. Fractures classes with distance between planes of weakness (Bruland, 1998)

Fracture Class (joints, fissures)	Distance between Plane of Weakness (mm)
0	-
0-I	1600
I-	800
I	400
II	200
III	100
IV	50

• **Joint orientation relative to tunnel axis:** In foliated, jointed rock, foliation or any other discontinuities can play an important role in rock fracture propagation between cuts, depending on the orientation of discontinuities with respect to the direction of machine advance. The influence of the joint orientation on TBM penetration rate is widely observed in tunneling projects. Wanner (1975) and Aeberli & Wanner (1978) observed that, the advance rate of TBM increases with the increase of the angle between the TBM axis and the planes of schistosity in a homogeneous zone of schistose phyllite. Yagiz (2002, 2008) observed that the angle between plane of weakness and the TBM driven direction (so called alpha angle) influence the TBM performance. As the angle ( $\alpha$ ) increases the penetration rate increases until reaches to 55-60°, then the ROP decreases with the increase of  $\alpha$  till 90 degrees (Figure 2.7).

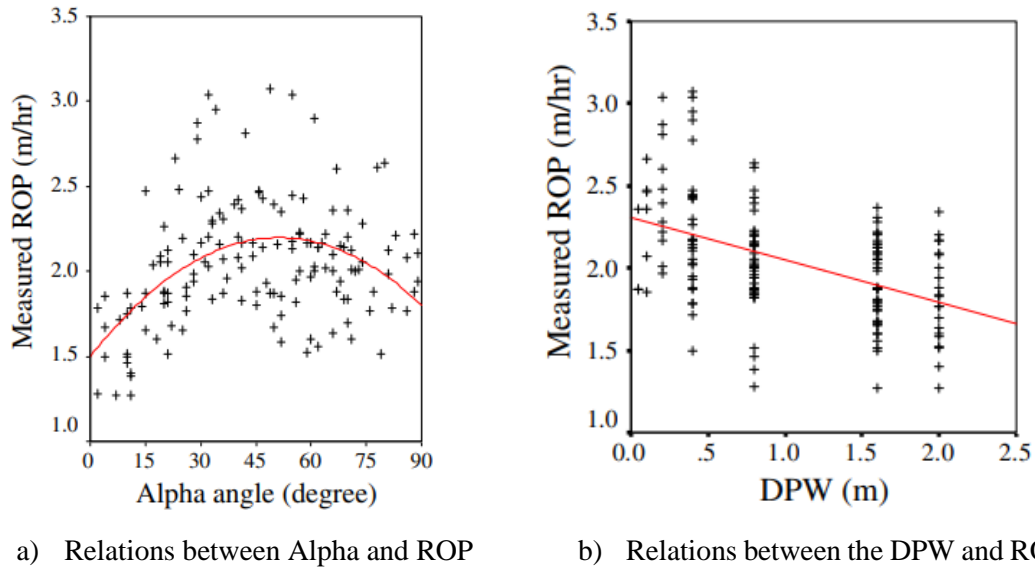

Figure 2.7. Effect of joint orientation and distance between the pane of weakness (DPW) on TBM penetration rate (Yagiz, 2008)

Gong et al. (2005) simulated effects of joint orientation on rock fragmentation by TBM cutters with series of two-dimension numerical modelling using the discrete element method (DEM-UDEC). They also stated the maximum TBM penetration is obtained when the alpha reaches at 60 degrees.

### 2.4.3. TBM Parameters and Specifications

The TBM specifications, such as thrust and power are the key to provide a sufficient amount of forces and torque to support the excavation operation. TBM thrust provides enough force to efficiently penetrate the rock mass. Also, the cutterhead torque and power enable the head to rotate at a designated penetration rate to overcome the rolling resistance. Generally, tougher rocks with less fractures and joints require more thrust and relatively low torque/power (due to low penetration), compared to soft/jointed rock where low thrust and high torque are expected (as a result of high penetration) (Salami, 2021). Cutter parameters (type, profile, material, tip width, and diameter) have a great influence on TBM performance. In particular, Roxborough and Phillips (1975)

and Bilgin et al. (2013) declared that larger cutters require higher thrust to obtain the same ROP for a rock mass, being disc-rock contact area larger. The thrust capacity increases when cutter diameter increases and, as a consequence, the ROP.

## **2.5. Existing TBM Performance Prediction Models**

Accurate estimation of both TBM penetration is of crucial significance for the successful completion of the mechanized excavation projects. It mainly includes the determination of the rock cutting force and efficiency under different cutter penetration depth and the determination of the optimum rock boring/cutting condition as well as tool consumption; however, this thesis focusses on the aspect of penetration prediction for hard rock tunnel boring machines. From past to present, many TBM performance estimation models are introduced (Graham 1976; Ozdemir 1977; Farmer and Glossop, 1980; Snowdon et al. 1982; Gehring, 1995; Rostami, 1997; Bruland, 2000; Barton, 2000; Yagiz 2002; Hassanpour, 2011; Wilfing 2014; Macias 2016; Yagiz 2008; Farrokh, et al. 2012; She et al. 2024) as summarized in Table 2.4.

Among those models, some are only based on simple one laboratory test and some based on practical tunnel construction data. Generally speaking, laboratory rock cutting tests on rock block are necessary, but they neither give a full picture of rock mass nor represent the full-scale operation of the TBM. A realistic prediction model should combine the laboratory tests data and site geological and rock mass conditions in the construction area. During the early period of TBM tunnelling and mechanized excavation, some simple empirical equations were developed from data on rock strength tests and force acting on a disc (Graham, 1976; Farmer and Glossop, 1980; Nelson, 1983; Huges, 1986).

Table 2.4. Summary of empirical equations developed for estimating the TBM penetration rate in the literature (Yazitova et al. 2025)

References	Equations	Inputs	Outputs
Grahan (1976)	$P_{rev} = 3940 \cdot F_n / \sigma_c$	$F_n, \sigma_c$	$P_{rev}$

Note: ROP, penetration rate (m/h);  $P_{rev}$ , penetration per revolution (mm/rev); RPM, cutterhead rotation speed (rev/min);  $F_n$ , cutter normal force (kN/cutter);  $\sigma_c$ , uniaxial compressive strength of intact rock (MPa);  $\sigma_t$ , tensile strength of intact rock (MPa); BI, brittleness index; D, tunnel diameter (m); d, cutter diameter (m); RQD, rock quality designation; RMR, rock mass rating; RSR, rock structure rating; Q, rock mass quality rating;  $Q_{TBM}$ , rock mass quality rating for TBM driven tunnels; GSI, geological strength index;  $\alpha$ , the angle between the tunnel axis and the joint plane;  $J_s$ , joint spacing;  $J_c$ , RMR joint condition partial rating; RME, Rock Mass Excavability;  $J_v$ , volumetric joint count; DPW, distance between the plane of weakness; PSI, peak slope index from punch penetration test;  $RT_c$ , artificial rock type code; q, quartz content;  $\gamma$ , rock unit weight ( $N/m^3$ );  $\nu$ , Poisson's ratio;  $K_v$ , the intactness index of rock mass; DRI, rock drillability index; c, cohesion; NTNU, Norwegian University of Science and Technology.

Later on, numerous TBM performance prediction models developed based on theory, laboratory test and field data. In the followings, common TBM performance prediction models used for estimating the TBM performance by means of the ROP is discussed briefly for the sake of the research. In the beginning of mid of 1970's up to present, numerous simple and also multivariable equations and models were developed from data related to rock properties and TBM parameters as given in Table 2.4. The commonly utilized equations are briefly introduced as below from simplest to the complex models for the aim of the research:

### 2.5.1. Simple Models

Graham (1976) derived a prediction equation based on a predominantly hard rock (uniaxial compressive strength from 140 to 200 MPa) database.

$$PR_{rev} = 624 \cdot \frac{F_n}{UCS} \quad (2.8)$$

Where,  $F_n$  and UCS refers to individual cutter thrust per cutter (kN/cutter) and uniaxial compressive strength (MPa) of rocks to obtained the rate of penetration ( $PR_{rev}$ ) in mm per revolution.

Farmer and Glossop (1980) established dataset to derive the equations base on sedimentary rocks.

$$PR_{rev} = 64 \cdot \frac{F_n}{BTS} \quad (2.9)$$

Where,  $F_n$  and BTS refers to individual cutter thrust per cutter (kN/cutter) and Brazilian tensile strength (MPa) of rocks to obtained the rate of penetration ( $PR_{rev}$ ) in mm per revolution.

Nelson et al. (1983) derived an equation from a comprehensive study on TBM

performance in sedimentary rocks such as shale, lime and sandstones.

$$R_f = 5.95 + 0.18 \cdot H_t \quad (2.10)$$

Where,  $R_f$  and  $H_t$  refers to field penetration index (kN/cutter/mm/revolution) and total hardness, which is the product of the rebound hardness (Schmitt hammer) and square root of the abrasion hardness.

### **2.5.2. CSM Models (1977, 1993, 2002)**

This model is the most famous semi-theoretical model developed by the Colorado School of Mines (CSM) approaches. The first version of the CSM model was developed by Ozdemir (1977) and also Ozdemir et al. (1978) using shear failure for performance prediction of V-shape disc cutters. After that, the model was updated by Rostami and Ozdemir (1993) and Rostami (1997) to predict the rock cutting force requirement of constant cross section (CCS) disc cutters at a given cut spacing and depth of penetration in a rock of known properties based on tensile failure. In fact, the CSM model estimates the individual cutter forces and consequently cutterhead thrust for a given penetration (mm/rev), based on rock properties including UCS and BTS of intact rock, and CCS disc cutter and cutting geometry. The formula can be used to estimate rock cutting forces for a given penetration accordingly maximum obtainable penetration for a given set of TBM and CCS cutter specifications in a given rock, through iterations. A large database of full-scale linear cutting machine (LCM) tests performed on rock samples in the CSM laboratory were used for development of the CSM model. Obviously, the LCM tests which were conducted on the rock block obtained from the field have proven to have some shortcomings when it comes to simulating rock mass conditions in the field, especially where the TBM performance is greatly influenced by joints and discontinuities

of rock mass. Based on the assumption and deduced functions by Rostami (1997), the total estimated resultant cutting force demonstrated in Figure 2.8 was derived as follows:

$$F_t = C \cdot T \cdot R \cdot \phi \cdot \left( \frac{\sigma_c^2 \cdot \sigma_t \cdot S}{\phi \cdot \sqrt{R \cdot T}} \right)^{1/3} \quad (2.12)$$

Where,  $F_t$  – total forces applying on disc (N);  $C$  – constant value (2.12);  $R$  – cutter radius;  $\sigma_c$  – uniaxial compressive strength (MPa);  $\phi$  – angle of the area of contact (rad);  $\sigma_t$  – tensile strength (MPa);  $S$  – cut spacing (mm). The angle of the area can be calculated using the following equation 2.13:

$$\phi = \cos^{-1} \left( \frac{R-p}{R} \right) \quad (2.13)$$

Where,  $p$  = penetration of cutter ( $mm/rev$ )

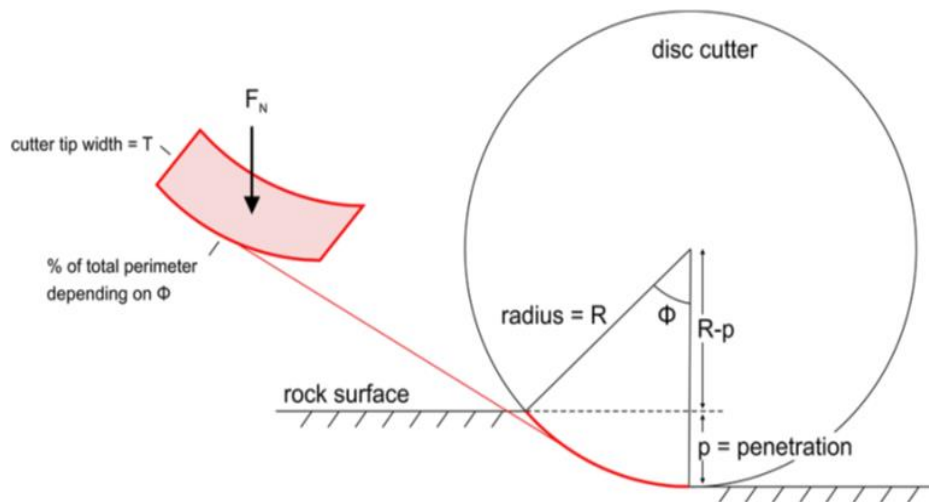

Figure 2.8. Diagram showing the interface region between disk cutter and rock  
(Rostami, 1997)

$$F_n = F_t \cdot \cos \left( \frac{\phi}{2} \right) \quad (2.14)$$

$$F_r = F_t \cdot \sin \left( \frac{\phi}{2} \right) \quad (2.15)$$

Where  $F_n$  is normal force and  $F_r$  is rolling force for individual cutters. This assumes of uniform pressure distribution  $\beta = \phi / 2$ , angle of the resultant force from the normal) in the contact area, which has been proved to be true (Rostami, 2008).

It is clear that the CSM model prediction based on intact rock strength (UCS and BTS) was not counting the influence of discontinuities on TBM penetration. The CSM model (1997) does not systematically incorporate rock mass fracturing in the prediction model, but later some modifications have been offered for considering the effect of rock mass conditions for the prediction of TBM performance by Yagiz (2002).

Yagiz (2002) developed a Modified CSM model (MCSM) to include the effect of rock mass fracture as a function of alpha, which is the angle between plane of weakness and TBM driven direction, and spacing between the fractures and brittleness to the basic prediction formula of Rostami and Ozdemir (Wilfing, 2016). The MCSM model is based on data from a 16 km long tunnel project where the author conducted geological mapping with a special focus on joint record, laboratory testing, and TBM field data analysis. The research results in the implementation of three more parameters to consider rock mass characteristics: fracture spacing ( $F_s$ ), orientation of discontinuities, and rock brittleness. For a quantitate description of discontinuities, Yagiz combined  $F_s$  and angle ( $\alpha$ ), to develop the rock fracture index (RFI). The rock brittleness index (BI) is determined by the peak slope ( $P_s$ ) measured by the punch penetration test (Eq. 2.16-2.17). Consequently, he proposed equation for predicting the ROP via MCSM model as a function of adjustment indices (RFI, BI) and CSM basic penetration ( $CSM_{b-rop}$ ) result as follow:

$$RFI = 1.44 \cdot \log(\alpha) - 0.0187 \cdot F_s \quad (2.16)$$

$$BI = 0.0157 \cdot P_s \quad (2.17)$$

$$\text{ROP} = 0.859 - \text{RFI} + \text{BI} + 0.969 \cdot \text{CSM}_{\text{b-rop}} \quad (2.18)$$

The main weakness for using this model outside the United States is the need of performing punch penetration tests for obtaining the BI. The test is commonly not used in European rock mechanics laboratories which makes the determination of BI complicated; however, Yagiz (2009) proposed conversion formula to provide a solution for this problem as in Eq.2.19.

$$\text{BI} = 0.198 \cdot \sigma_c - 2.174 \cdot \sigma_t + 0.913 \cdot \rho - 3.807 \quad (2.19)$$

Where,  $\sigma_c$ ,  $\sigma_t$ , and  $\rho$  refers to Uniaxial compressive strength (MPa), Brazilin tensile strength (MPa) and density of rock in kN/m<sup>3</sup>.

### **2.5.3. Gehring Model (1995)**

The prediction model, proposed by Gehring in 1995, is based on information from preceding literature and the author's observations in four cases from Voest-Alpine with a certain TBM setup as: Cutter diameter = 432 mm; Cutter spacing=80mm; and individual cutter force ( $F_n$ ) = 200kN. From the literature, several curves relating the TBM penetration rate to the intact rock's uniaxial compressive strength have been drawn (Figure 2.9) by applying the mentioned input parameters above.

Figure 2.9. TBM basic penetration recalculated from different sources (Gehring, 1995)

The final result is the maximum penetration for a certain normal force (such as 200kN) per cutter. The formula has a modular structure and a simple linear function with independent correction factors that allow the consideration of rock mass properties, as well as different cutterhead types and geometries (Eq. 2.20).

$$ROP = \frac{F_n}{\sigma_c} \cdot k_i \quad (2.20)$$

Where, ROP – penetration rate (mm/rev);  $F_n$  – net thrust per cutter (kN/cutter);  $\sigma_c$  – uniaxial compressive strength (MPa);  $k_i$  – correction factor

A correction factor  $k_i$  consist of  $k_0$ ,  $k_1$ ,  $k_2$ ,  $k_3$ ,  $k_4$  and  $k_5$  correction factors. The description of each correction factor is presented as the following:  $k_0$  – basic penetration;  $k_1$  – specific failure power;  $k_2$  – rock mass material;  $k_3$  – state of stress in rock mass;  $k_4$  – cutter diameters;  $k_5$  – cutter spacing.

Wilfing (2016) has modified the Gehring model (1995), called 'Alpine Model' for estimating the ROP. This approach introduces a new parameter named 'y-intercept BTS or LBC approach' in the original equation (Gehring, 1995) to assess the relation between the applied force ( $F_n$ ) and resulting ROP in hard rock tunnel boring. The new parameter depends on the LCPC (Laboratoire central des Ponts et Chaussées) breakability coefficient (LBC) and the Brazilian tensile strength.

#### **2.5.4. NTNU Model (1970, 1988, 1998, 2016)**

The NTNU model has been originally introduced in the later 1970s (Johannessen, 1976; Blindheim, 1979; Lislerud, 1988, 1997) and continuously revised and improved, as new tunneling data and TBM modifications become available. The 1998 version of the NTNU model (Bruland, 1998) is based on data more than 200 km of bored tunnels mostly in Norway. Contrary to many other models the uniaxial compressive strength is not considered as a significant factor in this model but fracturing degree of rocks. In fact, the boreability is expressed by drilling rate index DRI, which is a combination of rock brittleness value ( $S_{20}$ ) and Siever's miniature drill test ( $S_j$ ). The  $S_j$  value expresses rock surface hardness while the  $S_{20}$ -value includes the effect of rock brittleness and therefore grain size and grain boundary strength. Input parameters of this model can be divided into two main groups including rock/rock mass parameters, and machine parameters. These parameters also depend on various individual factors related to rock mass and TBM parameters. In fact, among the all rock properties, the degree of fracturing is the most important penetration parameters for tunnel boring herein. In the NTNU model, all parameters, related to rock mass, represented by Equivalent Fracturing Factor ( $k_{ekv}$ ), and all machine parameters represented by Equivalent Thrust ( $M_{ekv}$ ) (kN/cutter). Then;

$$i_0 = \left(\frac{M_{ekv}}{M_1}\right)^b \quad (2.21)$$

Where,  $i_0$ , main penetration rate (mm/rev);  $b$ , penetration coefficient;  $M_{ekv}$ , equivalent thrust per cutter (kN/cutter),  $M_1$ , critical thrust for 1mm/rev penetration (kN/cutter).

The term of equivalent thrust per cutter ( $M_{ekv}$ ), characterizes the influence of TBM parameters on the ROP and includes gross average cutter thrust, cutter diameter and cutter spacing. Parameters  $M_1$  and  $b$  are highly influenced by the factor  $k_{ekv}$ , which describes rock and rock mass properties such as spacing and orientation of discontinuities, drillability and porosity of the rock material (Bruland, 1998).

The obtained ROP in mm/rev could be converted to meter per hour as follow:

$$i_0 = i_0 \cdot \text{RPM} \cdot \left(\frac{60}{1000}\right) \quad (\text{m/h}) \quad (2.22)$$

Lastly, Macias (2016) revised the NTNU model. The update includes data from new projects, which increases the empirical basis of the data. Macias (2016) updated the fracture classification, classifying both joints and fissures; he also proposed the cutterhead velocity (RPM) correction factor. The optimal cutterhead velocity appears to be influenced by rock drillability, rock mass fracturing, and/or thrust level. Low values of and applied cutter thrust indicate a lower optimal cutterhead velocity (Macias, 2016; Wilfing 2016; Salimi, 2021). The updated formula is presented herein:

$$i_0 = i_0 \cdot \text{RPM} \cdot \left(\frac{60}{1000}\right) \cdot k_{rpm} \quad (\text{m/h}) \quad (2.23)$$

### 2.5.5. Barton Model (2000)

Based on the well-known Q-system (rock mass Quality) and data from 145 tunnels totaling more than 1000 km in length, Barton (1999, 2000) modified the Q-system into  $Q_{\text{TBM}}$  to predict TBM performance. The  $Q_{\text{TBM}}$  adds some new parameters

that take the interaction between TBM and rock mass into consideration. The components of  $Q_{TBM}$  are as follows:

$$Q_{TBM} = \frac{RQD_0}{J_n} \cdot \frac{J_r}{J_a} \cdot \frac{J_w}{SRF} \cdot \frac{SIGMA}{\frac{F^{10}}{20^9}} \cdot \frac{20}{CLI} \cdot \frac{q}{20} \cdot \frac{\sigma_\theta}{5} \quad (2.24)$$

Where,  $\frac{RQD_0}{J_n} \cdot \frac{J_r}{J_a} \cdot \frac{J_w}{SRF} = Q_0$ ; SIGMA – rock mass strength which can be divided by favorable/unfavorable inclination values; F – net thrust per cutter (tnf/cutter); CLI – cutter life index; q – quartz content (%);  $\sigma_\theta$  – biaxial stress (MPa).

An estimation of net penetration rate based on  $Q_{TBM}$  is presented in Eq. (2.25); further, the relationship between PR (m/hr), AR (m/hr), and  $Q_{TBM}$  is shown in Figure 2.10.

$$NPR \approx 5 \cdot Q_{TBM}^{-1/5} \quad (2.25)$$

Where, NPR – net penetration rate (m/h).

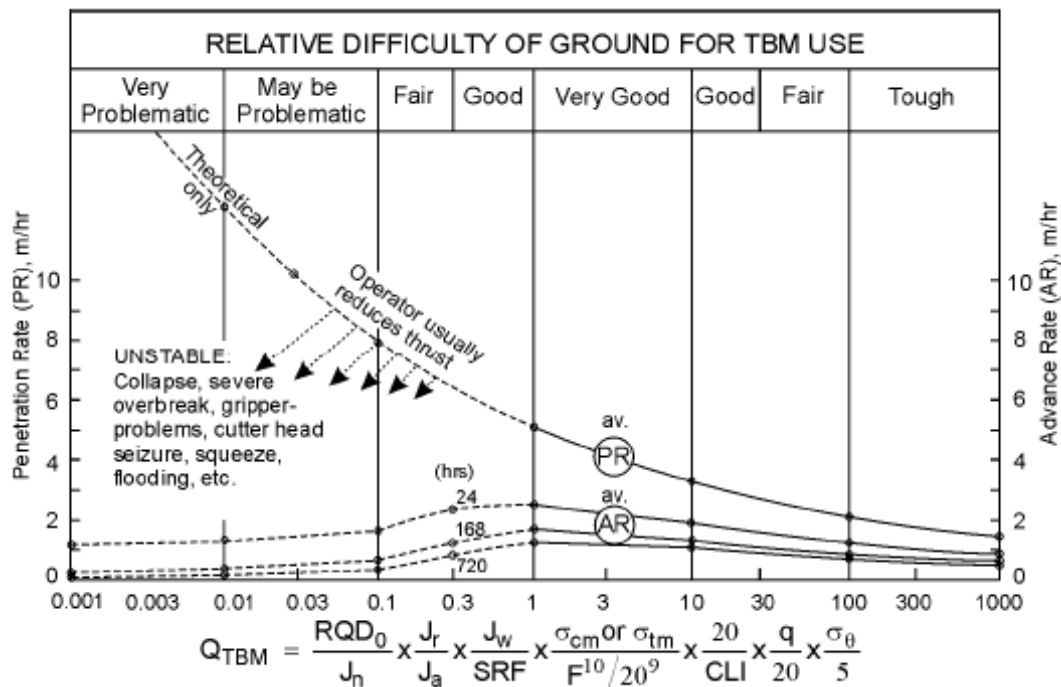

Figure 2.10. Suggested relations between the ROP, AR, and  $Q_{TBM}$  (Barton, 2000)

(2016) stated that the concepts behind this  $Q_{TBM}$  approach steps in the right direction, but the technical implementation is complicated and expensive. In sum, this model based on  $Q_{TBM}$  did not gain acceptance in the construction industry out of Norway since it contains numerous inputs, obtaining those inputs are commonly not easy in practice. Also, some of the laboratory tests such as cutter life index (CLI) and drilling index (DRI).

#### **2.5.6. Bieniawski et al (2006, 2007, 2008)**

Bieniawski, et al. (2006) developed Rock Mass Excavatability (RME) model which is similar to the RMR classification system to estimate performance of double-shield and open-type TBMs via advanced rate theoretically ( $ARA_T$ ). The RME input parameters are included drillability, stand-up time, UCS of intact rock, groundwater inflow, and discontinuities at the excavation front. The RME is computed using the mentioned input variables with their ratings (Table 2.5). The sum of the ratings of the RME parameters varies between 0 and 100 points and it is expected that the higher the RME value, the easier the excavation of the tunnel; consequently, achieving the highest production rate via the ROP. Further information related to RME model can be found in the literature (e.g., Bieniawski, et al. 2007). To predict theoretical average rate of advance ( $ARA_T$ ), Bieniawski, et al. (2008) proposed several equations for open TBM (Eq.2.26) and double shield TBMs (Eq.2.27) respectively using RME as below:

$$ARA_T = 0.324 \cdot RME - 6.8 \quad \text{If UCS} \leq 45 \text{ MPa} \quad (2.26)$$

$$ARA_T = 0.839 \cdot RME - 40.8 \quad \text{If UCS} > 45 \text{ MPa}$$

$$ARA_T = 0.661 \cdot RME - 20.4 \quad \text{If UCS} \leq 45 \text{ MPa} \quad (2.27)$$

$$ARA_T = 0.422 \cdot RME - 11.6 \quad \text{If UCS} > 45 \text{ MPa}$$

Table 2.5. The ratings for RME input parameters (Bieniawski et al. 2007)

Uniaxial Compressive Strength of intact rock [0-25]											
$\sigma_c$ (MPa)		<5	5-30		30-90		90-180		>180		
Rating		4	14		25		14		0		
Drillability – Drilling Rate Index [0-15]											
DRI		<80	80-65		65-50		50-40		<40		
Rating		15	10		7		3		0		
Discontinuities in front of the tunnel face [0-30 points]											
Homogeneity			Number of joints per meter					Orientation with respect to tunnel axis			
Homogeneous		Mixed	0-4	4-8	8-15	15-30	>30	Perpendicular	Oblique	Parallel	
Rating		10	0	2	7	15	10	0	5	3	0
Stand up time for TBM excavated tunnels [0-25 points]											
Hours		<5	5-24		24-96		96-192		>192		
Rating		0	2		10		15		25		
Groundwater inflow [0-5 points]											
Litre/sec		>100	70-100		30-70		10-30		<10		
Rating		0	1		2		4		5		

### 2.5.7. Yagiz (2008)

Yagiz (2008) developed TBM performance prediction model for hard rock mass rock condition using very detail and strong database obtained from Queens Fresh Water tunnel in 16km in New York City USA. The database composed of intact rock properties (such as UCS and BTS, Brittleness), rock mass properties including orientations and frequency of rock fractures with certain TBM set up (refers to TBM used for the Queens Fresh Water Tunnel in section 3.1).

$$ROP = 1.093 + 0.029 \cdot BI - 0.003 \cdot UCS + 0.437 \cdot \log(\alpha) - 0.219 \cdot DPW \quad (2.28)$$

where ROP – rate of penetration (m/h); BI – index of brittleness (kN/mm); UCS – uniaxial compressive strength (MPa);  $\alpha$  – the angle between the plane of weakness and TBM driven direction (°); DPW - spacing between planes of weakness (m).

Since the punch penetration test that is utilized for obtaining the BI, is commonly used in North America, but not available in many other countries around the world, Yagiz (2009) developed empirical formulate to obtain the BI as a function the UCS, BTS and density of rocks (refer to section 2.5.2). Further, the introduced equation is related to the conditions of Queens Water Tunnel and belonged single unique TBM; hence it can't be a reliable model to predict the performance of the TBM; however, the model is very common to be used in practice due to its simplicity.

#### 2.5.8. Farrokh et al (2012)

Farrokh, et al. (2012) have presented a model based on an analysis of a comprehensive database of more than 200 TBM projects records using multivariable statistical analysis. Multivariate regression was used to evaluate the data records, which included rock mass properties and system parameters, resulting in regression equations that were used to measure the ROP. Equation 2.29 is presented how penetration rate can be calculated based on Farrokh, et al. (2012) mode.

$$PR = \frac{F_n^{0.186} \cdot RQD_c^{0.133} \cdot RT_c^{0.183} \cdot RPM^{0.363} \cdot D^{5.47} \cdot e^{(0.046 \cdot D^2)}}{5.64 \cdot UCS^{0.248} \cdot e^{(1.58 \cdot D)}} \quad (2.29)$$

Where, PR – penetration rate (m/h);  $F_n$  – normal force of disc cutter (kN);  $RQD_c$  – rock quality designation;  $RT_c$  – rock type numerical code; RPM – rotational speed (rev/min); D – diameter of tunnel (m).

They stated that despite that the model is based on data from more than 200 projects, the equation that predicts the PR has a low regression coefficient. Due to the

model's limitations, it is strongly recommended to use this model in combination with other models, especially in more complex project situations (Farrokh et al., 2012).

### **2.5.9. Hassanpour et al. (2009, 2011, 2016)**

Hassanpour, et al. (2009a, b; 2011) developed an empirical TBM performance prediction model via Field penetration index (FPI) based on a database of actual machine performance from different hard rock TBM tunnelling projects in Iran. The database obtained from Iranian tunnels composed of shale, limestone, schist, tuff along the excavated tunnels. The relationship between different intact rock strength (UCS) and rock mass properties (such as, RQD) and cutter force ( $F_n$ ) is examined to obtain the best correlation among the available parameters to estimate the FPI in kN/c/mm/rev. They recognized the Field Penetration Index (FPI), defined as the ratio between the average individual cutter force ( $F_n$ ) and the ROP (Barton, 2000; Klein, et al. 1995), as the TBM performance parameter having the best correlation with the observed rock mass conditions; consequently, following equation is proposed:

$$FPI = \exp(0.008 \cdot UCS + 0.015 \cdot RQD + 1.384) \quad (2.30)$$

Where, FPI – field penetration index (kN/cutter/mm/rev) ; UCS – uniaxial compressive strength (MPa); RQD – rock quality designation.

Further, the rate of penetration (ROP) can be calculated by converting FPI to that.

$$ROP = \frac{0.06 \cdot RPM \cdot F_n}{FPI} \quad (2.31)$$

The formula and associated chart introduced by Hassanpour, et al. (2011) are very applicable/constructive and reflect the practical approach in an early stage of tunnel design and construction, since it has been developed based on two commonly available inputs including, and which are most often available in many tunneling projects around

the world; however, The model must be applied with caution in highly fractured rock masses and water sensitive rocks like marlstones and mudstones (Hassanpour et al., 2011).

#### 2.5.10. Yazitova et al (2025)

Recently, Yazitova, et al. (2025) introduced empirical models for estimating the TBM penetration rate using the big database related to six different tunnel projects around the world. The database including fractured hard rock, magmatic (such as granite, diorite), metamorphic rock (e.g., variety of gneiss, calc-silicate) through the sedimentary rocks including limestone, shale, tuff with the UCS of 20 to 300MPa (refers to chapter 4 in the thesis). Utilizing UCS of intact rock, cutter head diameter (CHD), frequency of fractures via weighted fracture index, WFI (Yagiz, et al. 2024), individual cutter force ( $F_n$ ) and RPM, TBM performance may be estimated by means of the ROP as follow:

$$ROP = \frac{F_n^{0.308} \cdot WFI^{0.136} \cdot RPM^{-0.027} \cdot CHD^{2.875}}{8.211 \cdot UCS^{0.101} \cdot e^{0.583 \cdot CHD}} \quad (2.32)$$

In order to develop the model, six TBM tunnels are examined in detail and then database including rock properties and TBM and disc cutter specification are established. After that, more than hundred linear and non-linear multiple regression models were developed, and the best accurate one in terms of statistical indices is suggested herein. It is found that the obtain equation (2.32) is reliable and useful for the TBM projects where the inputs variables are available to compute the ROP. Further, information and explanation for the developed models are available in this thesis.

## CHAPTER 3 : CASE STUDIES

In this thesis, the database was established using six different tunnel projects sources, those projects include Queens Water Tunnel USA; Manapouri hydropower tunnel New Zealand; Miryang Dam Tunnel S. Korea and Iranian Water Conveyance Tunnels including Karaj, Zagros and Ghomrood. Each of these tunnels was studied and raw data obtained from the laboratory and fields were also analyzed carefully for the aim. Intact rock, rock mass properties, TBM specification and Constant Cross Section (CCS) disc parameters are given in the database development section or related appendices for the aim of the research. Due to that, rock mass condition, intact rock properties and TBM specifications for each project are introduced in brief as follows.

### 3.1. The Queens Fresh Water Transfer (QFWT) Tunnel, USA

The Queens Fresh Water Tunnel # 3, stage 2 is intended to improve fresh water distribution throughout the City of New York, USA. The tunnel being about 7.5 km long and 7 m in diameter was excavated beneath Brooklyn and Queens at an average depth of 200 m below the sea level in West-central Queens County with using a high power TBM (Yagiz, 2008). New York City is located at the extreme southern part of the Manhattan schist, a northeast trending, deeply eroded sequence of metamorphosed Proterozoic to Paleozoic rocks into the crystalline terrains of New England (Baskerville and Mose, 1989; Merguerian, 1983, 1996). In construction area, geology is highly complex and composed of different metamorphosed igneous rock with shear zones, joint, faults, and other local weakness zones along the tunnel alignment. Five main geological formations have been identified in the area: Manhattan schist is composed of gray, medium to coarse-grained layered schist and gneiss. The Inwood Formation includes different types of marble units of white coarse-grained calcite–dolomite marble. Hartland Formation mainly consists of gray and gray weathered thinly laminated muscovite–biotite–quartz schist with minor

garnet. The Fordham Gneiss is a highly complex unit that includes black hornblende–biotite gneiss and white quartz plagioclase moderately banded gneiss (Merguerian, 2000). In the construction area, during tectonic orogeny, the Cameron’s Line ductile shear zone occurred. This zone is the major tectonic restrict between the Hartland formation and the Manhattan–Inwood–Fordham Sequence (Yagiz, 2008).

In this project, the main beam high power Robbins TBM (235–282) was equipped with both 0.482 m disc cutters and a rated load capacity of 30 tons per disc cutter to excavate the Tunnel. The basic specifications of the TBM are given in Table 3.1. The TBM operational data was analyzed throughout the tunnel, since the TBM specifications (i.e., thrust and power) are very important in providing sufficient amount of force and torque to carry out the excavation operation. In order to monitor the performance of the machine in the field, the TBM was fitted with an automatic state-of-the art data logging and recording system.

Figure 3.1. High Power TBM utilized for the Queens Fresh Water Transfer Tunnel (Yagiz, 2002)

All data derived from the control system of the machine were recorded on a standard personal computer connected to the control system via local connection (Yagiz, 2008). General specification of TBM and disc cutters are given in Figure 3.1. and Table 3.1.

Table 3.1. TBM specification for the Queens Fresh Water Transfer Tunnel

TBM Specification	Queens
Machine type (Open Beam)	Open*
Diameter (m)	7.10
Number of cutters	50
Cutter type	CCS Disc
Individual cutter diameter (mm)	482.6
Cutter tip width (mm)	19.05
Revolution per minutes (RPM)	8.3
Total cutterhead thrust (kN)	16000-18000
Cutter load (kN)	250-300
Field ROP (m/h)	1.89

\*Open refers to open type TBM

### 3.2. Manapouri Second Tail Race Hydropower Tunnel, New Zealand

The Manapouri Second Tailrace Tunnel is a significant hydroelectric infrastructure project in New Zealand, associated with the Manapouri Power Station, one of the country's largest hydroelectric power stations. The tunnel, completed in 2002, was constructed to enhance the efficiency and capacity of the power station by allowing more water to flow from Lake Manapouri through the power station to Deep Cove in Doubtful Sound. This second tunnel complements the original tailrace tunnel and significantly reduces the water pressure on the power station, increasing electricity generation capacity. The project involved extensive engineering, including drilling through hard rock and ensuring environmental sustainability in the ecologically sensitive Fiordland region (Kim, 2004). The geology of the tunnel is characterized by complex and challenging conditions due to the region's location within the Fordland area of New Zealand. The project site includes different types of rock including met-andesite, diorite,

hornblende biotite gneiss, biotite gneiss and calc-silicate gneiss with calc-silicate. In the location, with the presence of faults and fractures together with hard and abrasive rock, the construction of the tunnel was very challenging and it took more than expected to complete the project (Manapouri Project Report 2001; Kim, 2004).

Figure 3.2. TBM utilized for the Manapouri Second Tail Hydropower Tunnel (Kim, 2004)

Table 3.2. TBM specification for Manapouri Second Tail Hydropower Tunnel

TBM Specification	Manapouri
Machine type	Open
Diameter (m)	10.05
Number of cutters	68
Cutter type	CCS Disc
Cutter diameter (mm)	432
Cutter tip width (mm)	19.05
Revolution per minutes (RPM)	5.07
Total cutterhead thrust (kN)	17500-18150
Cutter load (kN)	275-300
Field ROP (m/h)	1.23

In the dataset herein, the 2km length of the tunnel (Reach 1) having 10m in diameter was examined and the raw data was extracted from report and literature and then analyzed. In this project open beam hard TBM were utilized to excavate the hard-abrasive rocks

encountered along the tunnel alignment. General specification of TBM and disc cutters are given in Figure 3.2. and Table 3.2.

### **3.3. Miryang Dam Tunnel, South Korea**

The main purpose of the project was to deliver clean water from Miryang dam to Yangsan area through 2.6m-diameter hydro-tunnel. A 5.4 km-long hydro-tunnel was driven by open hard rock TBM from March, 1997 to October 1999 in Miryang, South Korea. Total length of this hydro-tunnel was 7.6km through mountainous area in the country. According to geological site investigation studies along the project location, most of the tunnel alignment consisted of igneous rocks that are granite from fine to medium-grained rock. Especially fine-grained granite is a very abrasive and tough rock and the compressive strength of rock is various depend on the grain size and percentage of quartz in the rock.

Figure 3.3. TBM utilized for Miryang Dam Tunnel (Kim, 2004)

The project which is 7.6km long is located in a mountain area in the country. It is worth mentioning that excavation in the rock mass was very challenging due to high

compressive strength and abrasiveness encountered. This project used the Drill-Blast (DB) method and TBM excavation method simultaneously from both ends of the tunnel alignment.

Table 3.3. TBM specification for Miryang Dam Tunnel (Kim, 2004)

TBM Specification	Miryang
Machine type	Open
Diameter (m)	2.6
Number of cutters	22
Cutter type	CCS Disc
Cutter diameter (mm)	393.7
Cutter tip width (mm)	15.87
Revolution per minutes (RPM)	10.0
Total cutterhead thrust (kN)	4300
Cutter load (kN)	190-200
Field ROP (m/h)	1.0

The portion of DB and TBM-excavated tunnel having 2.6m in diameter in length was 2.2 km and 5.4 km, respectively (Kim, 2004; Yagiz, et al. 2010). A total of 24 months was spent to bore the 4.7 km TBM tunnel, and total boring hours were approximately 4.753 hours with a 32% TBM utilization (Kim, 2004). An open hard rock TBM (WIRTH, Model TB 260E) was used for this project (Figure 3.3) with TBM specifications and disc properties as given in Table 3.3.

#### **3.4. Zagros, Ghomrood and Karaj Water Transfer Tunnels, Iran**

Karaj, Zagros and Ghomrood Water Conveyance Tunnels (KWCT, ZWCT, and GWCT respectively) excavated in Iran were also examined and obtained data and findings were used for the establishment of the database herein. These tunnels are recently constructed in three different geological zone of Iran (Hassanpour, et al. 2009, 2011, 2018, 2024). The main group of rocks are sedimentary, metamorphic, volcanic, and pyroclastic rocks along the alignment of tunnels. Main structure of the rock mass

changes from massive to very blocky rocks, also seen some minor fault zones, foliation and folds along the tunnels.

Table 3.4. Specification of TBMs for Zagros, Ghomrood and Karaj Water Transfer Tunnel (Goodarzi et al. 2021; Hassanpour et al. 2011)

TBM Specification	Karaj	Zagros	Ghomrood
Machine type	DS*	DS	DS
Diameter (m)	6.73	6.73	4.53
# of cutters	42	42	35
Cutter type	CCS Disc	CCS Disc	CCS Disc
Cutter dia. (mm)	432	432	432
Cutter tip width (mm)	19.0	19.0	19.0
Revolution per minutes (RPM)	6.32	5.46	10.7
Total cutterhead thrust (kN)	17000	28134	18000
Cutter load (kN)	350-400	500-600	400-500
Field ROP (m/h)	3.82	2.45	3.02

DS refers to double shielded TBM

Since rock strength and rock mass properties including fracture spacing and frequency are more important than the type and mineralogical composition of rocks herein, detailed information related to geological formations and rock type was not given; however, those can be found in the literature (Goodarzi, et al. 2021; Yagiz, et al. 2024; Hassanpour, et al. 2024). Specifications of TBM used for the projects are given in Table 3.4 while the picture of TBM used for each project is illustrated in Figure 3.4-3.6.

Figure 3.4. TBM utilized for Ghomrood Water Transfer Tunnel (Hassanpour, et al. 2009)

Figure 3.5. TBM utilized for Karaj Water Transfer Tunnel (Hassanpour, et al. 2011)

Figure 3.6. TBM utilized for Zagros Water Transfer Tunnel (Goodarzi, et al. 2021)

As seen from the configuration and specification of the TBM, the rock encountered along the tunnels were soft to medium sedimentary or volcanic rock and the type of TBM used for the projects are double shielded one.

## CHAPTER 4 : DATA COLLECTION AND DATABASE ESTABLISHMENT

### 4.1. Data Collection

In this chapter, the selected and available projects mentioned in the chapter 3 are compiled and the database were established to use for development of empirical models to the estimation of the TBM performance in hard rock condition. The established database compiling the six different tunnel project's data has several sections including intact rock properties, rock mass properties, machine specification and TBM performance data from the field. In order to obtain the aim of the research, big database, more than 700 data points, was established using intact rock properties, rock mass properties, TBM specifications and disc parameters. After examining the several intact rock properties, uniaxial compressive strength (UCS) of intact rock was chosen to represent the strength of excavated rocks. Rock mass properties especially rock type, fracture frequency and spacing between the fractures were examined carefully to obtain two new indices which are fracture index (FI) and weighted fracture index (WFI). Also, TBM specification such as cutterhead diameter (CHD), RPM, number and diameter of discs ( $N_c$ ,  $D_c$  respectively) on a cutterhead and field performance parameters including cutter load ( $F_n$ ) and ROP were examined.

In the dataset, each project is examined carefully to not miss any rock or machine parameters that can be input variable for the models. After establishing the database and selecting input variables, the statistical range of the dataset is checked to find the limitation of model from the scope of data availability (Table 4.1). The examining the available and nominated input parameters including both rock properties, TBM specifications and disc parameters for the purposed models, the distribution of the data range (557 datapoints) in the dataset is also controlled by developing the histogram of

each variable as given in Figure 4.1-4.11. It is obvious that data distribution and the range of data in the used dataset for both training and testing datasets is very important for the developed model in practice.

Table 4.1. Statistical distribution of the range of input variables in the dataset

Parameters	# of data	Minimum	Maximum	Mean	Std. dev	Variance
SL <sub>c</sub> (m)	557	0.21	34.66	5.6222	6.81917	46.501
UCS (MPa)	557	20.00	300.00	155.8345	61.61448	3796.344
WFI	557	0.10	189.90	17.0537	33.02021	1090.334
MT <sub>c</sub>	557	1.00	2.00	1.1598	0.36674	0.134
F <sub>n</sub>	557	61.36	294.55	193.5709	65.53790	4295.217
CHD (m)	557	2.60	10.05	6.3505	2.30376	5.307
RPM (mm/rev)	557	5.07	10.70	7.9508	1.70355	2.902
N <sub>c</sub>	557	22.00	68.00	44.8474	14.47660	209.572
D <sub>c</sub>	557	0.39	0.48	0.4471	0.03571	0.001
ROP (m/h)	557	0.22	4.75	1.8159	0.89480	0.801

SL<sub>c</sub> and MT<sub>c</sub> refers to Length of tunnel segment excavate and TBM type respectively. MT<sub>c1</sub> and MT<sub>c2</sub> refers to O and DS respectively

Figure 4.9. Distribution of number of cutters on the cutterhead in the dataset

Figure 4.10. Distribution of cutter disc diameter in the dataset

Figure 4.11. Distribution of ROP in the dataset

In order to examine the impact of machine specification and properties on the tunnel scheduling and TBM performance assessment, TBM specifications are also examined (Table 4.2). TBM type, cutter head (CH) diameter, number of cutters on the CH, Cutter type, cutter diameter and tip width are also defined and used to establishment of the dataset. As a result, each TBM specification and possible parameter are assessed for the empirical models to obtain the most suitable input parameters for the most accurate model.

Table 4.2. TBM specification for each project in the database

TBM Specification	Queens	Manapouri	Miryang	Karaj	Zagros	Ghomrood
Machine type	Open*	Open	Open	DS*	DS	DS
Diameter (m)	7.1	10.05	2.6	6.73	6.73	4.53
# of cutters	50	68	22	42	42	35
Cutter type	Disc	Disc	Disc	Disc	Disc	Disc
Cutter dia. (mm)	482.6	432	393.7	432	432	432

Total thrust (kN)	16000	18150	4300	17000	28134	18000

\*Open and DS refer to Open Beam (gripper) and Double Shielded machines respectively

#### 4.2. Introducing of Rock Fracture Index (FI)

Fracture Index (FI), which represents the fracture count over an arbitrary length of rock with similar intensity of fracturing, provides insight into the state of blackness and joint frequency in rock masses (Yagiz, et al. 2024). Further, FI also impacts rock boreability in excavation operations. Fracture frequency (F) is defined as the number of natural discontinuities in a unit length of rock mass (i.e. per meter). The most reported quantitative measures of fracture state indices are Rock Quality Designation (RQD), average joint spacing, and FI. Both these fracturing indices provide an estimate of the degree of fracturing of rock masses. Sen (2014) proposed a geomechanical classification

method based on RQD and FI to characterize local zones of heterogeneities within a rock mass. A few studies have interpreted the relationship between FI and RQD (He, et al. 2021; Vali and Arpa, 2013; Wong, et al. 2023). So, several indices can represent fracture frequency and quality of rock mass relative to its joints and discontinuities. In this study, the degree of fracturing is examined to be quantified using as an input for estimating the TBM penetration.

**4.2.1. Degree of Fracturing**

The Norwegian Institute of Technology (NTNU) has developed a Fracture Class System for evaluating the penetration potential of complexly deformed rocks bored by a TBM (Bruland, 1998). Fracture Class is given a Roman numeral designation based on the average spacing of joints (Sp) or fissures (St) which together allow a Fracture Class Designation to be applied to a reach of the tunnel. The class includes both the spacing between and the type of weakness planes. This classification system is good and valuable based on the average spacing of joints and fissures, however, when spacing between planes of weakness is quantified in the field, may be the actual value can be used in the analysis instead of the classification (Project Report 1-83 1983; 1-94 1995; Bruland, 1998).

Table 4.3. Fracture Class Designation (Bruland, 1998)

Fracture Class	Distance between Plane of Weakness-DPW (cm)
0	Rock mass that is set as 200
0-I	160
I-	80
I	40
II	20
III	10
IV	5

#### 4.2.2. Fracture Index and Weighted Fracture Index Concept

Fracture index in number of fracture spacing/meter, is the number of clearly identifiable fractures per meter run of intact rock pieces or rock mass via scanline, measured over lengths of reasonably uniform rock. This index does not necessarily apply to whole core runs or along the rock mass excavated. If there is a marked change in fracture frequency during a core run, the fracture index should be calculated for each part of the run separately. In fact, FI is the quantification of fractures in certain amount of rock segment. Similarly, when dealing with rock mass, excavated segments of each rock mass should be considered separately to define the weighted fracture index (WFI) per segment (Yagiz, et al. 2024a) as follows:

$$FI = \frac{1}{DPW} \text{ (number of fractures spacing/meter)} \quad (4.1)$$

Where FI and DPW refers to fracture index and spacing or distance between the fractures for each rock class in meter, respectively and so;

$$WFI = FI \cdot SL_e \quad (4.2)$$

Where WFI and  $SL_e$  refers to the weighted fracture index (number of fracture spacing/excavated segment) and length of tunnel segment excavated respectively

After several scientific reports (Project Report 1-83 and 1-94 1995; Bruland, 1998), the NTNU fracture classification systems have been frequently used in literature by different researchers (such as Yagiz, 2002, 2008). However, most of the studies focused on the quantified value of the classification rather than the Roman numeral description to be used for mechanical rock excavation (such as Yagiz 2002; Merguerian and Ozdemir, 2003; Yagiz, et al. 2024b).

### **4.3. Establishment of Database**

Six TBM tunnel projects are examined for the aim of thesis to established database. After finding the number of inputs that is available for the model and the range of data for each variable, established database is used for development of new index that called fracture index (FI) and weighted fracture index (WFI) as mentioned previously.

In the database, the uniaxial compressive strength of intact rock, rock mass properties such as FI and WFI are introduced are the main rock related parameters. Further, TBM specifications including individual cutter load, cutterhead diameter, RPM, disc parameters such as number of discs on a cutterhead; tip width and diameter of CCS disc are added into database given as an example in Table 4.4. After that, the database is used for the development of empirical models by performing the SPSS Statistical program. Due to confidentiality, only limited datasets consisting of the rock properties and TBM parameters used in this research, are provided in **Appendix A and B**.

Table 4.4. Example of database used for the development of TBM Performance Model (see Appendices A and B)

## **CHAPTER 5 : DEVELOPMENT OF EMPIRICAL MODELS FOR PREDICTING TBM PENETRATION RATE**

In order to obtain predictive equations from the appropriate datasets for prediction TBM penetration rate, the SPSS Statistics (V.24, 2024) program was used as a statistical tool for this research. Using the SPSS (2024) program, simple linear, multiple linear and non-linear regression analyses were conducted, and the resulting equations examined to obtain the most accurate predictive models. A simple regression analysis was first performed between a single variable and rate of penetration in order to evaluate the influence of each individual parameter on ROP. Multiple linear and non-linear models were subsequently run in order to obtain the most accurate equations from the datasets.

### **5.1. Pearson Correlation Coefficients Among the Parameters in the Database**

It is well-known that to choose the input variables to estimate the unknown, the Pearson correlation among the inputs and outputs should be examined. For this reason, relations between the variable are assessed and the output of the findings is introduced in Table 5-1. The ROP and other input variable have some linear relations; however, these results are not strong enough to be solely used for the field performance of the TBM. As a result, it is found that the multiple variable and both linear and non-linear relations among the parameters should be examined and interpreted to obtain the most accurate estimation formulas for the aim.

To predict the penetration rate of the TBMs in the six tunnel cases, linear multivariable regression (LMR) and non-linear multivariable regression (NLMR) analyses were performed, after obtaining optimum valuable inputs via Pearson correlations among

the variables. To obtain the aim, numerous different LMR and NLMR models were developed with different input variables using the constructed dataset; however, five most accurate model generated from each modelling techniques were proposed herein to predict the ROP.

Table 5.1. Pearson Correlation among the input variables in the database

## 5.2. Simple Statistical Analysis

Commonly accepted methods to examine empirical correlations between variables are both simple and multiple regression methods using statistical software packages such as excel or SPSS statistics. In this study, linear ( $y=ax+b$ ) and non-linear ( $y=ax^b$ ) simple regression analyses were performed among intact rock and rock mass properties or TBM specifications and penetration rate. Rate of penetration (ROP) was used as a dependent value, while different intact rock and rock mass properties and machine parameters were used individually as an independent variable possible for prediction of TBM penetration rate. This resulted in several simple regression relations among the possible input variables and ROP. All results obtained with these simple models for prediction TBM penetration rate are summarized in Table 5-2.

Table 5.2. Simple models for prediction TBM penetration rate

#	Parameters	R <sup>2</sup>	Regression equation	Eq.
1	UCS	0.399	$ROP = 3.25 + 0.009 \cdot UCS$	(5.1)
2	SL <sub>e</sub>	0.346	$ROP = 1.382 + 0.078 \cdot SL_e$	(5.2)
3	FI	0.137	$ROP = 1.551 + 0.104 \cdot FI$	(5.3)
4	WFI	0.403	$ROP = 1.523 + 0.017 \cdot WFI$	(5.4)
5	Fn	0.011	$ROP = 2.098 - 0.001 \cdot Fn$	(5.5)
6	MTc	0.408	$ROP = -0.042 + 1.59 \cdot MTc$	(5.6)
7	CHD	0.001	$ROP = 1.76 + 0.009 \cdot CHD$	(5.7)
8	RPM	0.031	$ROP = 2.539 - 0.09 \cdot RPM$	(5.8)
9	Nc	0.001	$ROP = 1.89 - 0.002 \cdot Nc$	(5.9)
10	Dc	0.069	$ROP = -1.129 + 6.587 \cdot Dc$	(5.10)

### 5.3. Multiple Variables Statistical Analysis

The prediction of TBM ROP is either a linear or a non-linear multivariable problem. In order to consider the concomitant effects of intact rock and rock mass properties and TBM specifications on ROP, both linear and non-linear multivariable regression analyses were performed using the SPSS Version 24 (SPSS, 2024) statistical package. Non-linear regression consists in finding a non-linear model describing the relations between a dependent variable and a set of independent variables. In a multiple regression analysis, more than two variables including intact rock and rock mass properties and machine specifications are used to derive the correlation equation. In a multiple regression analysis, both linear and non-linear methods can be used, which result in different correlation coefficients, plots, histograms, means, standard deviations, etc. In order to evaluate the differences between the two methods in the multiple regression analysis, the results are presented in Tables 5.3-5.4

according to the type of regression. In order to conduct the models, dataset is divided in two part as 80% of it for training and 20% of it for testing.

### 5.3.1. Linear Multiple Variables Regression Models

After examining the relations among the inputs and output of the proposed models via Pearson correlation, LMR analysis is conducted to predict the ROP from alternative input parameters including rock properties such as intact rock strength, frequency of discontinuities in rock mass, and TBM specifications such as thrust, RPM, cutterhead diameter so forth. Simple regression-type equations could be extended to a multiple-variable concept by increasing the number of inputs as follows:

$$y = a + b_1x_1 + b_2x_2 + b_3x_3 + \dots + b_nx_n \quad (5.11)$$

Where  $x_1, x_2, x_3, \dots, x_n$  are different independent variables (e.g., UCS, WFI and  $F_n$ ) to predict  $y$  referring to the ROP herein.

Since one of the most common techniques is LMR to find the unknown from known variables, it is also utilized to obtain the aim in this study conducting numerous linear regression models by using the possible alternative inputs for both rock and TBM features. After trying various models with different input parameters, the five models that demonstrated acceptable performance were determined. These models can be seen in Table 5.3, where their prediction performance for the training dataset from the  $R^2$  point of view is presented. Comparing the output of the LMR models, Model 5 shows the most accurate model with a few meaningful input parameters among the other. As a result, obtained results from training and testing data are demonstrated in Figures 5.11-5.20 respectively. It can be

stated that LMR models are not reliable or enough accurate in comparison with the non-linear multiple regression modelling approach due to the complexity of nature and rock mass as experienced from the past. Due to that, NLMR models must be considered to find the best empirical equations with the most reliable input variables for the aim.

Table 5.3. Linear multiple regression equations developed using training dataset

Models #	R <sup>2</sup>	R	Regression Equations	Eq.
Model 1	0.516	0.718	$ROP = -0.005 \cdot UCS + 0.006 \cdot WFI + 0.63 \cdot MT_c + 1.703$	(5.12)
Model 2	0.525	0.725	$ROP = -0.009 \cdot UCS + 0.006 \cdot WFI - 0.016 \cdot N_c + 3.770$	(5.13)
Model 3	0.536	0.732	$ROP = -0.008 \cdot UCS + 0.004 \cdot WFI + 0.33 \cdot MT_c - 0.092 \cdot CHD + 3.213$	(5.14)
Model 4	0.569	0.754	$ROP = -0.009 \cdot UCS + 0.009 \cdot WFI + 0.561 \cdot CHD + 0.278 \cdot RPM - 0.08 \cdot N_c + 0.78$	(5.15)
Model 5	0.567	0.753	$ROP = -0.009 \cdot UCS + 0.01 \cdot WFI + 0.001 \cdot F_n + 0.195 \cdot RPM + 1.372$	(5.16)

In this research, there are more than 50 models with different alternative inputs was run by conduction linear multivariable regression analysis; however, the best five models were considered to present herein according to the accuracy of the LMR models. In puts, outputs and SPSS statistics results of the models are given in **Appendix B** in detail. Further, other best 20 models developed using the LMR approaches are added as **Appendix C**.

### 5.3.2. Non-Linear Multiple Variables Regression Models

Non-linear multiple regression (NLMR) is an approach to obtain a relation between independent as unknown and dependent variables. Unlike traditional simple linear regression, NLMR can be used to develop a model with random relationships between input and output variables, especially where complex engineering problems with multiple variables (Yagiz, et al. 2019). In the NLMR technique, both non-linear and linear relationships, such as exponential and power, can be employed as a hybrid. The NLMR approach is used for the establishment of mathematical formulas to make a prediction on dependent variables based on known independent variables in the geotechnical engineering fields in the literature (Armaghani, et al. 2016, 2017, 2021; Yagiz and Gokceoglu, 2010; Yagiz and Karahan, 2015; Yazitova and Yagiz, 2024). Using the constructed datasets, the best five NLMR equations were proposed to predict the rate of penetration as listed in Table 5.4 where the performance capacities (based on  $R^2$ ) of NLMR models are higher than those of LMR models. Based on NLRM, all models, including a variety of inputs such as  $F_n$ , CHD, UCS, RPM and WFI have the potential to be used for performance prediction of TBM; further, statistical analysis was conducted among the models using the statistical several indices together to select the best one via score ranking methods in this study.

Comparing the output of the NLMR models, each model gives enough accurate result with coefficient of determination ( $R^2$ ) higher than sixty five percent that means correlation coefficient ( $R$ ) of more than eighty percent. Each of them has potential to be used in practice; however, Model 1 is superior in comparison with others due to few input variables but ignorable low  $R^2$  in first glance. It is found that NLMR models are more reliable than the LMR models since the engineering problem is complex and not linear due to that, NLMR

models were considered to find the best empirical equations with the most reliable input variables for the aim.

Table 5.4. Non-linear multiple regression equations developed using training dataset

Model #	R <sup>2</sup>	R	Regression equations	Eq.
Model 1	0.666	0.816	$ROP = \frac{F_n^{0.308} \cdot WFI^{0.136} \cdot RPM^{-0.027} \cdot CHD^{2.875}}{8.211 \cdot UCS^{0.101} \cdot e^{0.583 \cdot CHD}}$	(5.17)
Model 2	0.669	0.818	$ROP = \frac{F_n^{0.26} \cdot MT_c^{0.05} \cdot N_c^{-0.823} \cdot RPM^{0.351} \cdot SL_e^{-0.041}}{0.098 \cdot UCS^{0.15} \cdot WFI^{-0.129} \cdot e^{(CHD \cdot D_c)^{-5.476}}}$	(5.18)
Model 3	0.652	0.808	$ROP = \frac{F_n^{0.354} \cdot WFI^{0.152} \cdot RPM^{0.007} \cdot CHD^{1.185}}{7.715 \cdot UCS^{0.119} \cdot EXP(0.023 \cdot CHD^2)}$	(5.19)
Model 4	0.668	0.817	$ROP = \frac{F_n^{0.266} \cdot RPM^{0.014} \cdot CHD^{2.996} \cdot SL_e^{0.042}}{9.22 \cdot UCS^{0.087} \cdot WFI^{-0.116} \cdot e^{0.591 \cdot CHD}}$	(5.20)
Model 5	0.653	0.808	$ROP = \frac{F_n^{0.347} \cdot CHD^{1.162} \cdot RPM^{0.046} \cdot MT_c^{0.095}}{8.765 \cdot WFI^{-0.145} \cdot UCS^{0.103} \cdot EXP(0.022 \cdot CHD^2)}$	(5.21)

Further, as result of NLMR models, obtained results from training and testing data are demonstrated in Figure 5.21 to 5.30 respectively. In order to examine the accuracy of each model in detail, the developed models via both LRM and NLRM are analyzed using evaluation metric including six different statistical indices together with total score ranking for each introduced model in the following section.

In this research, there are more than 50 models with different alternative inputs was run by conduction Non-linear multivariable regression analysis; however, the best five models were considered to present herein according to the accuracy of the models. In puts, outputs and SPSS statistics results of the models are given in **Appendix D** in detail. Further, other best 20 models developed using the NLMR approaches are added as **Appendix E**.

#### 5.4. Evaluation of Developed Models

To select the best LMR and NLMR equations for predicting the ROP, a score ranking method (Zorlu, et al. 2008) is used and the result of the analysis is summarized herein. Each performance (statistical) index was ordered in its class based on the capacity of models and the best total score of each model was found and assigned to obtain the highest rating among the models. In order to obtain the score ranking for each model,  $R^2$ , RMSE, RRMSE, MAD, MAPE and VAF were calculated and examined herein (Table 5.5). A score ranking values were calculated and assigned for each training and testing dataset separately to obtain detailed statistical indices (Table 5.6 to 5.9).

Table 5.5. Statistical performance indices used for determining the best model obtained in the study

Index	Evaluation Metric	Equations	Performance Description
1	Coefficient of determination	$R^2 = 1 - \frac{\sum_i (y_m - y_p)^2}{\sum_i (y_m - \bar{y}_p)^2}$	Higher values are better
2	Root Mean Square Error	$RMSE = \sqrt{\sum_{i=1}^N \frac{(y_m - y_p)^2}{N}}$	Lower values are better
3	Relative Root Mean Square Error	$RRMSE = \sqrt{\frac{\frac{1}{N} \sum_{i=1}^N (y_m - y_p)^2}{\sum_{i=1}^N (y_p)^2}}$	Lower values are better
4	Mean Absolute Deviation	$MAD = \frac{1}{N} \sum_{i=1}^N \frac{ y_m - m }{N}$	Lower values are better
5	Mean Absolute Percentage Error	$MAPE = \frac{1}{N} \sum_{i=1}^N \frac{ y_m - y_p }{y_m}$	Lower values are better
6	Variance Account For	$VAF = 1 - \frac{Var(y_m - y_p)}{Var(y_m)}$	Higher values are better

$y_m$ : measured values,  $y_p$ : predicted values,  $\bar{y}_p$ : the mean of the predicted values,  $m$ : mean,  $N$ : total observed sample,  $p$ : number of independent variables,  $Var$ : Variance

After computing the statistical indices of each model, score ranking is performed to obtain the best model. The computation of score ranking can be explained as follows. For example,  $R^2$  values of 0.516, 0.525, 0.536, 0.569 and 0.566 were obtained for train 1 to train 5 of the LMR technique, respectively (Table 5.6). Hence, their ratings were assigned as 1, 2, 3, 5 and 4, respectively. This procedure was repeated for each performance index as well as each predictive model (i.e. LMR and NLMR). After this process, the obtained ratings for each dataset (training and testing) were summed up separately (Table 5.7 and 5.9). For example, the rating values of the LMR training dataset 1 were assigned as 1 for  $R^2$ , 4 for RMSE, 3 for RRMSE, 5 for MAD, 4 for MAPE and 4 for VAF, so the performance rating was computed as 20 for training set (Table 5.6 to 5.9). The final stage of selecting the best models is to compute the total rank by summing up the rank value of each dataset (training and testing) as listed in Table 5.7-5.9 for LMR and NLMR. According to total rank values in these tables, Model 5 (with total rank of 41) and Model 1 (with total rank of 42) exhibited the best performance capacities for LMR and NLMR models, respectively.

## CHAPTER 6 : RESULTS AND DISCUSSIONS

In this study, empirical models consequently equations are introduced for the aim of industry, literature and academia. However, it is obvious that each model, -not only empirical, but also artificial intelligences (AI) models and theories, - has some advantages and disadvantages together with the capability and applicability of the models to the real-world problem. The most important contribution of this study to the literature is a dataset developed based on six different rock tunnels excavated into different rock types from sedimentary to gneiss rocks. Also, the obtained equations have very reliable input variables from both rock and machine specification points in practice. Since introduced WFI is a new input for estimating TBM penetration and the input parameters of these models are different than current models, comparing the output of the study with literature is not valuable. However, validation of each model was examined via testing part of the dataset.

To show the detailed quantified statistical indices of each model, the detailed score ranking of each model in LMR and NLMR are given in Figures 6.1 and 6.2 respectively. Model 5 for LMR and Model 1 for NLMR approaches are the most precise among the others. Since the problem is complex and non-linear, using NLMR is the best in comparison with linear approaches. Due to that Model 1 having less input the most accurate result obtained via NLMR is the best model among them. So, the models developed herein are crucially and significantly important for the industry. However, it should be noted that empirical models should be used for similar rock types and rock environments and geological conditions. So, the developed models herein should be used with care trying several empirical approaches both linear, non-linear or hybrid equations including both LMR and NLMR cases.

Figure 6.1. Visual presentation of ranking of the LMR models based on their performance.

Figure 6.2. Visual presentation ranking of the NLMR models based on their performance.

The most accurate NLMR model (Eq.5.17) is compared with actual ROP obtained in the field in Figure 6.3. It is also found that Model 5 (Eq.5.18) and Model 1 (Eq.5.20) show reliable agreement with the actual ROP along the tunnel chainage, for LMR and NLMR models, respectively. Further, the Model 2 (Eq.5.18) obtained via NLMR could be utilized alternatively in the situation where selection of machine type (MTc) has a priority in the early stage of tunneling project. It should be stated that the models developed herein are good enough to estimate the rate of penetration however, scheduling including time and money as well as safety is also an important part of the construction projects; due to that, obtained results should be one of the input variables to generate a design in tunneling rather than an independent parameter. Then, the output of the models may need to be adjusted based on different rock types, and the frequency of discontinuities along the tunnels. The accuracy of LMR are lower than the NLMR models any case (Tables 5.6-5.7). Also, the equations developed via NLMR are more applicable for reality since if one of these inputs is not available, those NLMR equations (Eq.5.17-5.21) yield to zero. On the other hand, LMR equations (Eq.5.12-5.16) still give some outputs that are not accurate or reliable in practice. Also, it should be mentioned that the models do not have input for the orientation of the discontinuities. That means the obtained output for any project should be adjusted according to the alpha angle obtained as a function of tunnel direction and orientation of discontinuities in the rock mass.

Figure 6.3. The result of the NLMR Model 1 in comparison with Actual ROP obtained in the field

## CHAPTER 7 : CONCLUSIONS AND RECOMMENDATIONS

### 7.1. Conclusions

In this thesis, numerous LMR and NLMR equations were developed using a variety of input parameters including both rock properties and machine specifications. After that, the best five LMR and five NLMR models were obtained and introduced to the literature. To select the input variables for the models, Pearson correlations and simple regression among the variables in the dataset are conducted. Then equations obtained via multiple variable regression and statistical analysis are introduced herein. To decide the best one among the developed models, statistical indices including  $R^2$ , RMSE, RRMSE, MAD, MAPE, and VAF are evaluated and the total score ranking method is used for the final decision. Based on the findings, it is stated that Model 1 developed using the NLMR approach is the most accurate one among them, since the total ranking score of the Model 1 is the highest at 42 with few input variables (Eq.5.17). Furthermore, some other models such as Model 5 for LMR and Model 2 for NLMR both having total score ranking at 41, also show good results in comparison with others; however, with high score ranking and a few reliable inputs including UCS, CHD,  $F_n$ , WFI and RPM, Model 1 via NLMR is the best capability and applicable; so, it deserves to be credited. It is concluded that the model should be used for similar rocks ranges from sedimentary to igneous and granitic gneiss as in dataset; on the other hand, the orientation of discontinuities in the rock mass, weathering degree and other unquantified rock features e.g., textural coefficient of rocks also should be considered in practice. Due to that, the developed model has the potential to be updated using the mentioned parameters of the rock mass for future research consideration.

## 7.2. Recommendations

In this research, empirical models are developed for the estimating TBM penetration rate in rock mass. As inputs variable, the models include the properties of intact rock, rock masses and also TBM specifications to obtain the aim. Inputs of the multi variable linear and non-linear models developed are: The uniaxial compressive strength of intact rocks; discontinuity frequency and properties in rock mass as a fracture index and weighted fracture index obtained via rock mass properties; TBM specifications including individual cutter load, RPM, CHD. It is obvious that the model obtained is reliable and acceptable from practical point of view to be used for TBM projects. However, as every model has, developed models also have some room to be improved. From this point of view, obtained models including Eq.5.17 or other non-linear multivariable models, may need some extra inputs to account of variables that influence the TBM penetration. It is known that texture of rock, rock brittleness, and also alpha angle, the angle between the plane of weakness (fractures) and TBM driving direction, have also impact on the output of the models. Due to that, the introduced models may be improved by adding those inputs such as alpha angle and texture coefficient or brittleness index into the model equations; however, these improvements should be made with care since the database used herein is very comprehensive and including wide range of rock properties and rock types and also several projects.

## **Nomenclature**

AI	= Artificial Intelligent
AR	= Advance Rate
BI	= Brittleness Index
BTS	= Brazilian Tensile Strength
CCS	= Constant Cross Section
CHD	= Cutter Head Diameter
CLI	= Cutter Life Index
CM	= Continuous Miner
CSM	= Colorado School of Mines
Dc	= Diameter of discs
DB	= Drill-Blast
DEM-UDEC	= Discrete Element Method
DPW	= Distance between Planes of Weakness
DRI	= Drilling Rate Index
$F_n$	= Cutter force
FI	= Fractured Index
RFI	=Rock Fracture Index
FPI	= Field Penetration Index
GWCT	= Ghomrood Water Conveyance Tunnel

KWCT	= Karaj Water Conveyance Tunnel
LDS	= Longwall Drum Shear
LBC	= Breakability Coefficient
LCM	= Linear Cutting Machine
LMR	= Linear Multiple Regression
MAD	= Mean Absolute Deviation
MAPE	= Mean Absolute Percentage Error
MCSM	= Codified CSM Model
MTc	= Machine Type code
Nc	= Number of discs
NLMR	= Non-linear Multiple Regression
NPR	= Net Penetration Rate
NTNU	= Norwegian Institute of Technology
PR	= Penetration Rate
QFWT	= Queens Fresh Water Transfer
$R^2$	= Coefficient of determination
RBM	= Raise Boring Machine
RME	= Rock Mass Excavatability
RMSE	= Root Mean Square Error
ROP	= Rate of Penetration

RPM	= Revolution Per Minutes
RRMSE	= Relative Root Mean Square Error
RQD	= Rock Quality Designation
RTc	= Rock Type code
SER	= Specific Excavation Rate
SLe	= Length of tunnel segment
S <sub>p</sub>	= Spacing of joints
S <sub>t</sub>	= Spacing of fissures
SP	= Specific Penetration
TBM	= Tunnel Boring Machine
TH	= Cutterhead net Thrust
UCS	= Uniaxial Compressive Strength
VAF	= Variance Account For
WFI	= Weighted Fracture Index
ZWCT	= Zagros Water Conveyance Tunnel

## Appendix C

### SPPS Program Output for the Best Five LMR Models

### Model 1-Linear Multiple Regression Model

Model	Variables Entered/Removed <sup>a</sup>		Method
	Variables Entered	Variables Removed	
1	MT <sub>c</sub> , UCS, WFI <sup>b</sup>	.	Enter

a. Dependent Variable: ROP

b. All requested variables entered.

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.719 <sup>a</sup>	.516	.513	.62221

a. Predictors: (Constant), MT<sub>c</sub>, UCS, WFI

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	182.205	3	60.735	156.880	.000 <sup>b</sup>
	Residual	170.730	441	.387		
	Total	352.935	444			

a. Dependent Variable: ROP

b. Predictors: (Constant), MT<sub>c</sub>, UCS, WFI

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	1.703	.202		8.445	.000
	UCS	-.005	.001	-.336	-8.042	.000
	WFI	.006	.002	.233	4.058	.000
	MT <sub>c</sub>	.630	.145	.253	4.349	.000

a. Dependent Variable: ROP

$$\text{ROP} = -0.005 \cdot \text{UCS} + 0.006 \cdot \text{WFI} + 0.63 \cdot \text{MT}_c + 1.703$$

End

## Model 2-Linear Multiple Regression Model

Model	Variables Entered/Removed <sup>a</sup>		Method
	Variables Entered	Variables Removed	
1	N <sub>c</sub> , WFI, UCS <sup>b</sup>	.	Enter

a. Dependent Variable: ROP

b. All requested variables entered.

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.725 <sup>a</sup>	.525	.522	.61633

a. Predictors: (Constant), N<sub>c</sub>, WFI, UCS

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	185.418	3	61.806	162.708	.000 <sup>b</sup>
	Residual	167.517	441	.380		
	Total	352.935	444			

a. Dependent Variable: ROP

b. Predictors: (Constant), N<sub>c</sub>, WFI, UCS

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	3.770	.272		13.880	.000
	UCS	-.009	.001	-.620	-10.285	.000
	WFI	.006	.001	.222	4.121	.000
	N <sub>c</sub>	-.016	.003	-.266	-5.267	.000

a. Dependent Variable: ROP

$$\text{ROP} = -0.009 \cdot \text{UCS} + 0.006 \cdot \text{WFI} - 0.016 \cdot \text{N}_c + 3.770$$

End

### Model 3-Linear Multiple Regression Model

Model	Variables Entered/Removed <sup>a</sup>		Method
	Variables Entered	Variables Removed	
1	CHD, WFI, MT <sub>c</sub> , UCS <sup>b</sup>	.	Enter

a. Dependent Variable: ROP

b. All requested variables entered.

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.732 <sup>a</sup>	.536	.532	.61016

a. Predictors: (Constant), CHD, WFI, MT<sub>c</sub>, UCS

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	189.127	4	47.282	127.003	.000 <sup>b</sup>
	Residual	163.807	440	.372		
	Total	352.935	444			

a. Dependent Variable: ROP

b. Predictors: (Constant), CHD, WFI, MT<sub>c</sub>, UCS

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	3.213	.402		7.989	.000
	UCS	-.008	.001	-.585	-8.262	.000
	WFI	.004	.002	.157	2.650	.008
	MT <sub>c</sub>	.330	.158	.133	2.089	.037
	CHD	-.092	.021	-.245	-4.312	.000

a. Dependent Variable: ROP

$$\text{ROP} = -0.008 \cdot \text{UCS} + 0.004 \cdot \text{WFI} + 0.33 \cdot \text{MT}_c - 0.092 \cdot \text{CHD} + 3.213$$

End

#### Model 4-Linear Multiple Regression Model

Model	Variables Entered/Removed <sup>a</sup>		Method
	Variables Entered	Variables Removed	
1	N <sub>c</sub> , WFI, RPM, UCS, CHD <sup>b</sup>	.	Enter

a. Dependent Variable: ROP

b. All requested variables entered.

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.754 <sup>a</sup>	.569	.564	.58851

a. Predictors: (Constant), N<sub>c</sub>, WFI, RPM, UCS, CHD

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	200.891	5	40.178	116.008	.000 <sup>b</sup>
	Residual	152.044	439	.346		
	Total	352.935	444			

a. Dependent Variable: ROP

b. Predictors: (Constant), N<sub>c</sub>, WFI, RPM, UCS, CHD

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.780	.639		1.221	.223
	UCS	-.009	.001	-.606	-8.953	.000
	WFI	.009	.001	.350	6.378	.000
	CHD	.561	.311	1.497	1.807	.071

Derivatives are calculated numerically.

a. Major iteration number is displayed to the left of the decimal, and minor iteration number is to the right of the decimal.

b. Run stopped after 49 model evaluations and 23 derivative evaluations because the relative reduction between successive residual sums of squares is at most  $SSCON = 1.00E-008$ .

#### Parameter Estimates

a. Major iteration number is displayed to the left of the decimal, and minor iteration number is to the right of the decimal.

b. Run stopped after 54 model evaluations and 25 derivative evaluations because the relative reduction between successive residual sums of squares is at most  $SSCON = 1.00E-008$ .

## Academic CV of PhD candidate

# Aitolkyn Yazitova

✉ aitolkyn.yazitova@nu.edu.kz 📞 +77055126863 📍 Astana

## Education

<b>PhD in Mining Engineering</b> Nazarbayev University, Astana, Kazakhstan	2020 – 2025
<b>Master's Degree in Mining Engineering</b> Nazarbayev University, Astana, Kazakhstan	2017 – 2019
<b>Bachelor's Degree in Petroleum Engineering</b> Kazakh-British Technical University, Almaty, Kazakhstan	2013 – 2017

## Employment

<b>Research assistant</b> Nazarbayev University, Astana, Kazakhstan Geochemical study of the corrosion at Uzen oil field	2019 – 2020
<b>Internship</b> Kazzinc Shakhtostroy, Ridder, Kazakhstan Determining drilling directions underground using a theodolite in a mine	2018 – 2018
<b>Internship</b> Kazakhoil Aktobe, Aktobe, Kazakhstan Compilation of technical reports concerning the Kozhasai field.	2017 – 2017
<b>Internship</b> Karachganak Petroleum Operating B.V., Aksay, Kazakhstan An introductory exploration into the separation of gas and liquid phases and the utilization of compressors for gas re-injection to maintain reservoir pressure equilibrium	2016 – 2016

### Participating in conferences/forums

<b>ConnectEd2024</b>	2024
<b>Mining &amp; Exploration Forum (MINEX)</b>	2019
<b>Volunteer of the IX Central Asian MINEX</b>	2018
<b>New Generation. Across the Universe</b> forum in Moscow	2016
<b>Organizer of the SPE VI, VII International Scientific and Practical Conference " Problems of innovative development of the oil and gas industry</b>	2015

### Honors & Awards

<b>Selected as one of the eight young rock engineers to participate in the 9th ISRM Early Career Forum</b> New Delhi, India	2024
<b>Participant of intellectual game "GeoGames"</b>	2016
<b>1st place in the regional intellectual team game "GeoQuestions"</b>	2016
<b>The winner of Kurmangazy Petroleum Company 2016- 2017 Scholarship</b>	2016
<b>1st place in The VII International Scientific and Practical Conference 'Innovative Development Problems in Oil and Gas Industry' with project 'Kinematics of a parallel Mechanisms with two-end effectors</b>	2015
<b>Marathons, participating in 10km and 21km distances several times</b>	

### Qualities

- Hardworking and responsible
- Effective communication and presentation skills
- Team player
- Outstanding abilities in organization
- Capacity to rapidly grasp scientific software applications
- Pursuing advancement and personal development in a professional capacity
- I take pleasure in upholding discipline
